[0011] Embodiments of the disclosed RF energy harvesting circuit improve the sensitivity of RF energy harvesting circuits over the related art power harvesting circuits.

[0012] According to an aspect of the present invention, there is provided an RF power harvesting device including an inductor, a first capacitor connected to the inductor, a first MOSFET connected to a first node, and a second MOSFET connected to the first node, and the inductor or the first capacitor are connected to the first node.

[0013] In the RF power harvesting device, values of the first MOSFET and the second MOSFET are such that intrinsic capacitances of the first MOSFET and the second MOSFET and the inductor constitute a substantially resonant circuit during operation of the RF power harvesting device.

[0014] The RF power harvesting device of claim **1** further includes a second capacitor connected to a second node, and the second MOSFET is connected to the second node, wherein the second MOSFET is a PMOSFET.

[0015] The RF power harvesting device further includes a receiver which detects and receives ambient RF energy, and the first capacitor and the receiver are connected at a third node, the first capacitor and the inductor are connected in series at a fourth node, and the inductor is connected to the first node.

[0016] The RF power harvesting device further includes a first set of resisting elements connected to a first gate of the first MOSFET to apply a first DC bias to the first gate, and a second set of resisting elements connected to a second gate of the second MOSFET to apply a second DC bias to the second gate.

BRIEF DESCRIPTION OF THE DRAWINGS

[0017] The above and other features and advantages of the present invention will become more apparent by describing in detail exemplary embodiments thereof with reference to the attached drawings in which:

[0018] FIG. **1** illustrates a single stage of a related art Villard voltage doubler circuit.

[0019] FIG. **2**. illustrates a power harvesting device, according to an exemplary embodiment of the present invention.

[0020] FIG. **3** illustrates a power harvesting device, according to an exemplary embodiment of the present invention.

[0021] FIGS. **4**(*a*)-(*b*) illustrate different placements of a matching inductor and a DC blocking capacitor and the associated lossy parasitic capacitance and resistance, according to an exemplary embodiment of the present invention.

[0022] FIG. **5** illustrates a layout of a power harvesting device, according to an exemplary embodiment of the present invention.

[0023] FIG. **6** illustrates a power harvesting device, according to an exemplary embodiment of the present invention.

[0024] FIG. **7** illustrates biasing the gate of diode-connected MOSFETs, according to an exemplary embodiment of the present invention.

[0025] FIG. **8** illustrates a circuit design implementing sacrificial current biasing, according to an exemplary embodiment of the present invention.

[0026] FIG. **9** illustrates an ideal diode response of a diode connected MOSFET with regular FETs and a diode connected MOSFET using low threshold voltage FETs.

[0027] FIG. **10** shows a power harvesting device, according to an exemplary embodiment of the present invention.

[0028] FIG. **11** illustrates the layout of RF harvesting circuits to form a silicon integrated circuit, the layout including five RF power harvesting circuits, which are the physical implementations of the harvesting circuits shown in the circuit schematics shown in other figures, according to an exemplary embodiment of the present invention.

[0029] FIG. **12** illustrates a comparison of measured RF to DC conversion efficiency versus output voltage between a power harvesting device with sacrificial biasing, and a power harvesting device without biasing.

[0030] FIG. **13** illustrates a self-powered system.

[0031] FIGS. **14**(*a*)-(*b*) illustrate different types of batteries implemented in the system shown in FIG. **13**.

[0032] FIG. **15** illustrates a schematic of a switched capacitor DC-DC converter.

[0033] FIG. **16** illustrates a three stage converter operation for 0.35V input at 20 Hz switching using 100 uF external capacitors.

[0034] FIG. **17** illustrates the frequency dependency of a 1000 uF capacitor charging with 0.35V input and three 100 uF external storing capacitors.

[0035] FIG. **18** illustrates the discharging test results for 60 hour charging (1 KΩ) load, 0.2 Hz clock signal) with a rigid battery.

[0036] FIG. **19** illustrates the discharging test results for 4 hour charging (1 KΩ load, 25 Hz clock signal) using two chips with a rigid battery.

[0037] FIG. **20** illustrates a switching signal generated by a ring counter using four flip-flops.

[0038] FIG. **21** illustrates four converter charging results—(a) Vin=0.35V for a rigid battery, (b) Vin=0.4V for a rigid battery, (c) Vin=0.45V for a rigid battery, and (d) Vin=0.45V for a flexible battery.

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

[0039] The present invention will now be described more fully with reference to the accompanying drawings, in which exemplary embodiments of the invention are shown.

[0040] One embodiment of the present invention provides a modified power matched Villard voltage doubler circuit, compatible with modern complementary metal-oxide-semiconductor (CMOS) processes, which demonstrates the ability to harvest RF electromagnetic energy that is available at power levels as low as in the microwatt range. Revisions to the Villard voltage doubler have been made and accessory circuitry has been added to provide it with the ability to harvest energy from power levels as extremely low as tens of μWatts (micro) low power levels. In the related art, relatively large values of input power of hundreds of μWatts or even higher are required to utilize a Villard voltage doubler topology. The reason for this it that the general Villard voltage doubler topology utilizes rectifying diodes which need to be turned on in order to transform AC currents and voltages into DC currents and voltages, so that their intrinsic energy can be stored. However, turning on these diodes requires several tenths of a volt, and a relatively large amount of input power is typically required to generate these voltages.

[0041] The present invention provides several modifications to the Villard voltage doubler topology, which modifications allow it to harvest energy from very low power levels and go beyond the limitation previously set by the threshold level of the rectifying diodes. For instance, one embodiment of the present invention provides resonant reactive elements are incorporated in a CMOS circuit that allows for the generation of relatively large voltages, without the need for large power, in order to turn on the rectifying diodes. The Villard circuit topology is implemented in an actual CMOS process making it realizable for fabrication as an integrated circuit in modern technology. Certain parasitic elements of the CMOS process are utilized to increase voltage levels and improve circuit performance (typically, parasitic elements limit circuit performance).

[0042] Application specific circuit layout designs are disclosed so that the effect of other parasitic elements would be minimized. Diode connected CMOS devices are used instead of standard diodes to implement the Villard topology. Furthermore, in one embodiment, instead of using an n-type metal-oxide-semiconductor field-effect transistor (NMOSFET), one of the diode functions is implemented using a p-type MOSFET (PMOSFET) polarity. This embodiment mostly eliminates the body effect and allows for the diode connected MOSFETs to be turned on at a lower voltage, thereby giving rise to a lower threshold power in order to obtain AC to DC conversion and allow for energy storage at lower power levels. In another embodiment, a set of sacrificial bias resistors is used to increase the gate voltage of the MOSFETs, and thereby turn them on at a lower voltage which allows for further sensitivity and increases energy harvesting. In addition, in yet another embodiment, circuit blocks are stacked in series to generate even high DC voltage levels from microwatt levels of electromagnetic RF energy.

[0043] It is desirable to integrate the power harvesting circuits of the disclosed embodiments onto CMOS integrated circuits. To accomplish this, the diodes can be replaced with diode connected MOSFETS M**1** and M**2**, as illustrated in FIG. **2**. This modification has an advantage in that it can be naturally fabricated using a CMOS process. Furthermore, using diode connected MOSFETs gives added flexibility for establishing an adjustable effective diode turn on voltage.

[0044] An inductor L**1** can be added near the input power source (RF source) as shown in FIG. **2**. This helps give rise to a matching circuit. In addition to the standard concept of matching, which allows for maximum power transfer from a fixed source impedance, the inductor works in concert with the parasitic intrinsic capacitances usually associated with a MOSFET gate to generate a very large voltage across the reactive components (discussed below in further detail). The generation of such a large voltage is one advantage of using the power harvesting circuit shown in FIG. **1**. Specifically, the generation of the large voltage facilitates the turning on of the CMOS diode connected devices at low incident power levels in order to achieve efficient AC to DC conversion, and ultimately energy storage. Thus, instead of the parasitic intrinsic capacitances functioning to reduce the frequency response and be detrimental to CMOS circuit performance, their reactive nature when working in concordance with the added input inductor L**1** allows for generation of large voltages which will ultimately make the power harvesting device more sensitive to harvesting RF energy. This circuit has a complex impedance that mainly consists mainly of a reactive part.

[0045] A. Modification to Matching Inductor and use of Intrinsic Capacitance for Large Voltage Generation and Diode Turn-On.

[0046] As mentioned previously, in order to be able to utilize the Villard voltage doubler topology, it is necessary to achieve voltages sufficiently large to turn on the diodes (or diode connected MOSFETs) D**1** and D**2**. However, this is difficult if the power of the input signal is very low, in the microwatt range, for example. To overcome this problem, reactive components are utilized in the design which are able to accumulate relatively large amounts of AC power over time, and thus generate voltages that are sufficiently large to turn on the diodes, and thus harvest RF energy even at power levels as low as microwatts.

[0047] The reactive elements that generate the large voltages for turn on are shown in FIG. **3** (e.g., the inductor L**1**, and the intrinsic MOSFET capacitors C_{GS1}, C_{SB1}, C_{GS2}, and C_{SB2}). The inductor L**1** is used to resonate with the capacitive structures intrinsic to the MOSFETs themselves and the fabrication process. The inductor L**1** is an accessory element constructed on the chip. However, instead of adding an accessory capacitor network to generate the complementary reactive impedance, the capacitors that are typically deemed as parasitic and detrimental to circuit performance are utilized in the current embodiment. More specifically, the intrinsic source-gate capacitance (C_{GS1}, C_{GS2}), and the source-body capacitance (C_{SB1}, C_{SB2}) associated with the two diode connected MOSFETS (M**1** and M**2**), are used.

[0048] From FIG. **3**, it can be seen that that accessory inductor L**1** and the intrinsic capacitors C_{GS1}, C_{SB1}, C_{GS2}, and C_{SB2} together form a series resonant circuit. The values of these intrinsic capacitors are in the Femto-Farad range. Furthermore, the capacitors C**1** and C**2** are orders of magnitude larger than the aforementioned CMOS intrinsic capacitors, and thus have negligible impedance at the frequencies of interest (hundreds of MHz to GHz). As such, impedances of the capacitors C**1** and C**1** can be neglected. Considering the relative magnitudes of the intrinsic capacitors with respect to C**1** and C**2**, the intrinsic capacitors can be considered to be at AC ground. Since this is the case, the intrinsic capacitors are in parallel with the gate-source junction of the diode connected MOSFETs. Thus, when large voltages are generated across the capacitive reactive elements, large voltages are also generated across the gate-source voltages (V_{GS}) of the MOSFETs, thereby turning them on and allowing them to operate as rectifiers.

[0049] The optimal response of the circuit is obtained at an input frequency where the accessory matching circuit (comprising of L**1** and the intrinsic capacitors) is in resonance. This condition maximizes the voltage at the input (point B in FIG. **3**) of the circuit, and matches the source impedance of an attached antenna (or any power source) to the complex conjugate of the input impedance of the circuit. Assuming the input power source (i.e., the RF source) has a real source impedance, it can be derived that as long as the following expression (1) is true then the voltage at the input is maximized when the complex impedance (Z_{load}) at the input is matched to the source impedance Rs in FIG. **3** (Rsource in expression 1).

$$\sqrt{\frac{|Z_{load}|}{R_{source}\cos(\phi)}} > 2 \tag{1}$$

[0050] In expression 1, ϕ is the phase difference between the voltage and current wave form. This is equivalent to the phase difference between the real and imaginary components of the load impedance.

[0051] While achieving resonance is optimal for performance, the power harvesting circuit also performs well even when not at resonance. This is because, even at frequencies that are as much as 20% away from resonance, large voltages are still generated across the reactive components, specifically the intrinsic capacitors. These voltages are also in parallel with the gate-source voltage (V_{GS}) of the diode connected MOSFETs, thereby turning them on and allowing for energy harvesting even at power levels in the microwatt range.

[0052] B. Performance Improvement with Parasitic Aware Circuit Layout

[0053] While a schematic diagram of an electronic circuit is an abstraction, once that circuit is constructed into a silicon chip the performance of the current changes. One reason for this is that the physical implementation of passive structures, including inductors, capacitors and interconnects, gives rise to unintentional or parasitic elements. For example, laying out of an on-chip inductor gives rise to unintentional capacitors from the inductor to the substrate ground.

[0054] In one embodiment of the disclosed power harvesting device, performance enhancement can be achieved by switching the order of the impedance matching inductor L**1** and the DC blocking capacitor C**1**, as illustrated in FIG. **4*b***. While theoretically the schematic shown in FIG. **3** is independent of the order of the L**1**-C**1** pair, it becomes apparent after examination of the parasitics incurred during layout, that the schematics in FIG. **3** (also see FIGS. **4*a***) and **4*b*** are different. The schematic produced by the layout shown in FIG. **4*b*** is less sensitive to the negative parasitics associated with the capacitor C**1**.

[0055] In particular, the impedance to voltage doubler at point A in FIG. **3** is dominated by the intrinsic capacitances of the diode connected MOSFETs (C_{GS1}, C_{SB1}, C_{GS2} and C_{SB2}). Therefore, it appears as a short at the RF frequency and the impedance at point B is also highly reactive. The parasitic capacitance of C**1** results in an imaginary impedance parallel to the input impedance at point A and B. This imaginary impedance serves to reduce the magnitude of the complex impedance and reduce the phase difference between the imaginary and real part of the complex input impedance. It can be seen from the expression (2) below that this will reduce the magnitude of the voltage at the input to the voltage doubler.

$$|V_{load}| = \frac{V_{source}}{2}\sqrt{\frac{|Z_{load}|}{R_{source}\cos(\phi)}} \tag{2}$$

[0056] By switching the order of the capacitor C**1** and the inductor L**1**, as in FIG. **4***b*, the reactive part of the impedance at points D and E is tuned out generating a large resonant voltage across the MOSFET capacitors, resulting in a real impedance on the order of 10 to 100 ohms. This is orders of magnitude lower than any parasitic impedance to the substrate due to C**1**. Therefore, the circuit in FIG. **4***b* shows superior performance to the circuit in FIGS. **3** and **4***a* in the presence of parasitic capacitances from C**1**.

[0057] This improvement can also be understood as follows. If one considers the operation of the resonant voltage generator circuit, one realizes that the largest voltages are generated at point B and the lowest voltage exist at the node connecting inductor L**1** and the source resistor Rs in FIG. **3**. Therefore, in the current embodiment, the parasitic capacitor and parasitic series resistor are moved away from the highest potential in the circuit to the lowest potential in the power harvesting circuit by switching the order of the inductor L**1** and the capacitor C**1**. While this has no effect on the theoretical operation of the circuit with respect to a schematic (done without regard to actual layout and fabrication), it greatly improves actual operation by placing the parasitic elements at a lower voltage where they will draw substantially less current, and thereby minimize their negative impact on power harvesting circuit's operation.

[0058] Another implementation of this concept is performed with the layout of inductor L**1**. The inductor L**1** is implemented on two metal layers of the CMOS process. The lower layer, which is closer to the substrate, gives rise to larger parasitic capacitance and substrate resistance. Therefore, the inductor L**1** is fabricated with the lower layer location placed at the location where the circuit voltage is lowest. This location is the side of inductor L**1** that is closer to the input and specified by point D in FIG. **4***b*.

[0059] It should also be noted that modern processes such as the IBM 8 RF process require that a certain ratio of gate tiedowns to metal area be maintained. Connecting the inductor L**1** directly to the gate of NMOS **2** (e.g., M**2** in FIG. **2**) in a Villard voltage doubler would require an unrealistic number of tiedown contacts. Therefore, this technique is best suited for designs that use a PMOS in place of NMOS **2** as discussed below.

[0060] C. Use of PMOS to Reduce Body Effect

[0061] FIG. **5** illustrates a power harvesting circuit with an NMOSFET (e.g., M**2** in FIG. **2**) replaced with a PMOSFET (PMOS in FIG. **5**). In a steady state, an NMOS **2** (e.g., M in FIG. **2**) will have a source potential that is significantly higher than the body potential. This gives rise to an increase in the threshold voltage of NMOS **2** through the body effect. This causes the diode connected NMOS **2** to turn on at a higher voltage, thereby reducing efficiency. To minimize the body effect in the current embodiment, NMOS **2** is replaced with a diode connected PMOS, as shown in FIGS. **3** and **5**. The PMOS has the body, gate, and drain node connected to Vout and the source node connected to the voltage at the source terminal of the diode connected NMOS **1**. The body effect of NMOS **1** (e.g., M**1** in FIG. **2**) is already minimized and is treated similar to M**1** in FIG. **2**. The PMOS only conducts when the gate voltage is below the source voltage. Since the gate has been connected to Vout, this occurs when the AC voltage at the input is positive with respect to ground. Since both the body and the source of the PMOS are connected to Vout, no threshold voltage increase occurs due to the body effect. This improvement can be combined with the other embodiments discussed above, including the embodiment shown in FIG. **3** where the order of the capacitor C**1** and the inductor L**1** are transposed to reduce parasitic capacitive and resistive losses.

[0062] In order for the design to work, the PMOS needs to be sufficiently isolated to allow connecting the body of the PMOS to Vout without any current flowing from the PMOS body to the bulk substrate. Connecting the body of a diode connected PMOS to Vout is possible due to the fact that PMOS FETs are placed in an n doped well inside of the p substrate.

[0063] As seen in FIG. **6**, the PMOS is built in an N well. Since the junction from the N well to the P substrate acts as a diode, if the voltage potential in the N well is higher than the voltage potential in the P substrate, current will not flow. This is what allows the body to be connected to Vout which is higher than the potential of the substrate. The junction capacitance between the N well and the substrate is parallel to and several orders of magnitude lower than the output capacitance C**2** of the power harvesting circuit. Therefore, the junction capacitance has no significant effect on the circuit performance.

[0064] D. Sacrificial Biasing

[0065] The output voltage of the related art voltage doubler is two times the input voltage minus the threshold voltage of both diodes. Therefore, minimizing the threshold voltage of the diodes maximizes the voltage at the output of the voltage doubler. Previous works in the related art have attempted to improve RF power harvesting efficiency by using special MOSFETS with reduced gate threshold voltages.

[0066] In an exemplary embodiment of the present invention shown in FIGS. **7** and **8**, an alternative technique uses biasing at the gate combined with the use of a PMOS in place of the output NMOSFET to eliminate the threshold voltage for both diode connected MOSFETs.

[0067] For example, in the embodiment shown in FIG. **7**, voltage sources are directly connected to the gates of the diode connected MOSFETs in the RF power harvesting circuit.. An alternative approach is to use the desired output voltage to create the bias voltages through a voltage divider network, as shown in FIG. **8**. This technique sacrifices some current to create an overall improvement to system efficiency. In this embodiment, the NMOS **2** is replaced by a PMOS IN FIG. **8** for two reasons. First, the threshold voltage of the output diode connected MOSFET must be below Vout to be obtainable through a voltage divider network. Second, the gate is connected to a DC node in the circuit. Sufficiently larger resistors R**1**, R**2**, R**3**, and R**4** are used in the divider network IN FIG. **8** to reduce power dissipated due to the bias current. The resistors are chosen to be 1 MΩ to 10 MΩ for 10 μW input power. Generally, the smaller the input power, the higher the resistances. This power dissipation can be designed to be orders or magnitude below the increase in output power due to the bias voltages. Practical limitations are placed on the size of the resistors used in the divider network due to a physical limitation of the resistor size in the circuit layout.

[0068] In the current embodiment, traditional MOSFETs outperform low threshold voltage MOSFETs when sacrificial current biasing is utilized. This is in contrast to related art literature that has concluded that the use of low threshold voltage MOSFETs provides the best performance for RF power harvesting. So, instead of using low threshold voltage MOSFETs, we have introduced sacrificial biasing while using regular MOSFETs and have achieved improved results. The improvement is because we achieve the effect of easily turning on the MOSFETs, while retaining the improved performance of regular MOSFETs with respect to the turn on characteristics as shown in FIG. **9**. Regular MOSFETs, have a sharper turn-on transition than low threshold voltage MOSFETs resulting in a faster turn on when transitioning to the open state, showing better RF conversion efficiency.

[0069] FIG. **10** illustrates a comprehensive design of a power harvesting device which includes the transposition of the inductor L**1** and the capacitor C**1** of FIG. **4***b*, the implementation of the PMOS device in place of M**2** as shown in FIG. **5**, inclusion of sacrificial bias resistors R**1**-R**4** as shown in FIG. **8**, as well as implicit utilization of MOSFET intrinsic capacitors for achieving maximum turn on voltages with low power input as shown in FIG. **3**.

[0070] FIG. **11** is the layout of the harvesters to form a silicon integrated circuit. The layout shows five RF power harvesting circuits, which are the physical implementations of the harvesting circuits shown in the circuit schematics shown in other figures. The circuits have been used to compare and test the various designs of the energy harvester. The testing provided the data that has lead to the conclusion and claims in this patent application.

[0071] FIG. **12** illustrates a comparison of measured RF to DC conversion efficiency versus output voltage between a power harvesting device with sacrificial biasing, and a power harvesting device without biasing. The harvester with sacrificial biasing achieves high efficiency compared with unbiased design for 1V output voltage. The higher curve represents a higher conversion efficiency for RF energy into DC energy. That is, the results show that for the given output voltages, the sacrificial biasing provides improved efficiency over the unbiased design.

[0072] FIGS. **13**-**21** relate to self-powered systems. An RF power harvesting device discussed with respect to the above embodiments is incorporated. Available RF power is sometimes very weak, so it is not easy to generate a sufficient output for direct use. Using a combination block, converter, and battery provides an attractive solution.

[0073] FIG. **13** shows a block diagram of self-powered system including an RF power harvesting block **1**, a voltage converter **2**, a battery **3**, a combined block **4**, and functional electronics **5**. Here, the RF power harvesting block **1** could be one of the RF power harvesting devices discussed in the above embodiments.

[0074] In one embodiment, the converter **2** is a switched-capacitor DC-DC voltage converter. The converter is designed to generate maximum six times of input voltage at output using external capacitors. Through capacitor charging tests, it shows up to 40.5% energy transfer efficiency using 0.35V input for a 1000 uF capacitor charging to 1.4V during 10 minute with a three stage converter. The battery **3** can be a rigid type battery or a flexible type battery. Both types of batteries are successfully recharged using the converter **2**. In one embodiment, two hour charging with four parallel converters recharges a rigid battery fully with 0.4V input, so it returns the battery potential to the initial condition before discharging of a 9.85 KΩ load resistor during 10 minutes.

[0075] The rigid type electrochemical battery comprises hydrated Ruthenium Oxide ($RuO_2.xH_2O$) and activated Carbon (CA). These cells have high current capacity, rechargeability, and even flexibility. One of the targets of the battery **3** is playing a role of the power source for distributed sensor networks, or Smart-dust nodes, for achieving a stand-alone system. Much research in the related art has been focused on implementing self-powered systems such as a node of low-power ad hoc distributed networks using an RF power harvesting device. However, when the input power at RF harvesting block **1** is very small, the output is not enough to drive a system or node (e.g., the functional electronics **5**). This problem can be solved by using a voltage converter **2** and rechargeable battery **3** combination block **4**, as shown in FIG. **13**. For example, a DC voltage converter **2** stacks the small voltage of RF energy harvesting block **1** up to the necessary charging voltage for battery cell and charges a battery **3**. Then, the battery **3** provides enough bias or power for the system (e.g., functional electronics **5**) only when it needs to be working. In the current embodiment, a switched-capacitor DC voltage converter is used as the converter **2** for battery charging. This converter **2** and battery **3** combined block **4** bridges a gap between RF power harvesting block **1** and functional electronics **5**, e.g., in insufficient RF power environments. So, it can help to implement a self-powered or stand alone system more effectively.

[0076] Usually, the developed battery cells have 1.1V~1.2V built in potential after fabrication without any other charging or discharging steps, and slightly higher charging voltage than the built in potential was fine for battery recharging. Actually, charging voltage and time for constant voltage charging scheme show a trade-off relation. A 1.4 charging voltage of DC power supply is used during two hours for full recharging. FIG. **14** shows two types of batteries, a rigid battery (FIG. **14**(*a*)), and a flexible battery (FIG. **14**(*b*)).

[0077] Switched-Capacitor DC-DC Converter

[0078] There are two reasons why we choose a switched-capacitor scheme for DC-DC converter among several different types. The first is its simplicity of implementation, and the second is it needs capacitors for storing energy. The second factor is advantageous because the battery cells can be used as a capacitor also by some modifications. So the switched-capacitor method is a very attractive one.

[0079] FIG. **15**(*a*) shows the schematic of a switched capacitor DC-DC converter with three stages. A single chip is implemented using IBM8RF 0.13 um CMOS process including every switch for a five stage converter, except external capacitors. That is, maximum available output voltage is six times of input voltage through five external capacitors, and the output can be selected by a user from minimum (input×1) to maximum (input×6) just connecting an external capacitor's plus pad to input.

[0080] In the schematic, the top switches are made by nMOS only, but the middle and bottom switches are made by transmission gate, combining nMOS & pMOS to transfer the accumulated potential on each capacitor to the next stage without any loss. The converter works on two different phases. For capacitor storing phase ($Q=1$, $\overline{Q}=0$ FIG. **15**(*b*)), the input node is connected to every external capacitor, so all capacitors are in parallel. However, the output is disconnected from the converter. In this step, external capacitors are charged up through input. Then, during battery charging phase (Q=0, $\overline{Q}$=1,

[0081] FIG. **15**(*c*)), the parallel configuration of capacitors is changed into series, and the output is connected to the last capacitor's plus node. Note the input can be used in both phases without any waiting or sleeping mode. So, it can decrease the charging time by fully using the input source. FIG. **16** shows the output (~1.4V) of the converter using a three stage converter for 0.35V input at 20 Hz clock signal using 100 uF three external capacitors. Note the body contacts of pMOS in converter switches are connected into external 1.5V DC power supply. This external source can be replaced with a battery for fully self-powered system implementation.

[0082] Big Capacitor Charging

[0083] At the initial tests of the converter, a big capacitor, 1000 uF, replaces a battery for charging test to verify functionality of the converter, just using three stages. Also, frequency dependency is checked for different clock signals of 50% duty cycle. The external capacitors, storing energy from input voltage, and input voltage are fixed as 100 uF and 0.35V, respectively. FIG. **17** shows the results of capacitor charging for different clock signals, and the inner graph is a magnified version of 400~700 sec section. All tests are stopped when the capacitor voltages reach 1.38V, except 20 KHz test. The plots for 2 Hz, 20 Hz, and 200 Hz test are almost overlapped. As listed in Table 1, 2 Hz and 20 Hz test have almost same results for energy transfer efficiency, around 40%, and charging time about 10 minutes, where the supplied energy is calculated by integrating the measured current from power supply and the stored energy is just calculated value using $\frac{1}{2}CV^2$. As the clock frequency goes higher, the saturation voltage goes lower. It is caused by frequency dependency of dynamic power consumption of CMOS switches [6]. By frequency dependency tests, a 0.2 Hz~20 Hz clock frequency range is used for battery charging tests.

TABLE 1

Frequency dependency of 1000 uF capacitor charging properties

Clock Frequency [Hz]	Charging Time [sec]	Supplied Energy [mJ]	Stored Energy [mJ]	Energy Transfer Efficiency [%]
0.2	953.5	2.352	0.952	40.48
2	611.5	2.349	0.952	40.53
20	617.5	2.394	0.952	39.77
200	629.5	2.555	0.953	37.30
2K	755.5	2.755	0.953	34.59
20K*	755.5	3.010	0.852	28.31

*For 20 KHz test, 1.3 V saturated voltage is used for calculations.

[0084] Battery Charging

[0085] The test procedure follows three steps for battery charging: 1) initial discharging, 2) cell charging, and 3) discharging.

[0086] The first charging test set up is 0.3V input from power supply, five 100 uF external storing capacitors for a five stage converter, which provides 1.8V output without load, and 50% duty cycle 0.2 Hz clock signal. Actually, a test with 0.25V input, making 1.5V output by five stages, was performed, but the charging time took over several days. So, to reduce charging time, input voltage is increased from 0.25V to 0.3V. FIG. **18** shows the test results. After the initial discharging (dashed line) during 1280 seconds, the load voltage was dropped from 0.485V to 0.223V for 1 KΩ load resistor. The black solid line shows the discharging after 60 hours charging. 60 hours charging gives 0.316V initial load voltage, when 1 KΩ load is connected to the battery after charging. Though the charging time, 60 hours, is a little long, we demonstrate a DC-DC converter is working properly for the battery charging.

[0087] To reduce charging time, the input voltage is increased from 0.3V to 0.34V and two converters are used in parallel for another test. Clock signals are applied for two converters to operate in opposite mode at the same time. That is, if a converter is in capacitor storing mode, the other is in battery charging mode. The test setup is 0.34V input, generating 2V output without load due to using five stage, and 25 Hz clock signal with 50% duty cycle. The battery cell is discharged with 1 KΩ load during 20 minute before charging, as shown by the dashed line in FIG. **19**, and load voltage drop is measured from 0.358V to 0.174V. Then, two converters charge the cell for 4 hours. This leads to 0.29V initial load voltage at discharging after charging (solid line in FIG. **19**). Using higher input voltage and two converters, the charging time is effectively reduced from 60 hour to 4 hour.

[0088] Another charging test is performed using four converters for further decreasing charging time. To run four converters together, switching signals are generated using a ring counter, which is made by four D Flip-Flops. FIG. **20** shows the generated timing diagram of the counter, Q_0~Q_3. Simply, inverters inverse each timing signal for the reverse switching signal inputs, $\overline{Q_0}$~$\overline{Q_3}$. Using the switching signals, if Q_0 is high, only one output of converters is connected to battery cell, and the others are in capacitor storing mode.

[0089] During capacitor storing mode, external capacitors are in parallel, so it gives a high total capacitance. Accordingly, it makes a long RC time constant for capacitor storing. Previous tests used five stages with 100 uF external capacitor, which gave 500 uF total capacitance for capacitor storing mode. For quick charging up capacitors, only three stages are used for other tests, which need three external capacitors for each converter. However, reducing the number of stage affects the output voltage directly. To compensate for this, higher input voltage is used. Also, higher input voltage can reduce the charging time further by providing more charges on storing capacitor, if the current capacity of the input signal is not limited. In the following tests, 0.35V, 0.4V, and 0.45V input are used for comparison.

[0090] Four charging tests are performed using a rigid (Test 1~3) and flexible (Test 4) type battery. For a rigid battery, charging time is limited to 2 hour, but the flexible cell is charged for 12 hours due to the cell's own property. Usually, the flexible battery consumed more current at the same charging voltage compared with rigid one. Furthermore, 9.85 KΩ and 100.2Ω load resistor are used at discharging for rigid and flexible battery, respectively. The test results and setup are shown in FIG. **21** and Table 2.

[0091] Every charging test shows energy recovery of battery. Although 2 hour charging with 0.35V input is not sufficient for full recovery before discharging, other two tests, Test 2 & 3, show the fully recovered battery potential compared with discharging before charging tests. However, Test 3 does not give any improvement in spite of higher input voltage, 0.45V. This may be due to the aging of the cell through several charging and discharging tests. Test 4 shows 12 hour charging result for flexible cell.

TABLE 2

Charging test setup and results

							Discharging during 10 minutes			
			Charging (three stage converter)				Before charging [V]		After charging [V]	
	Battery Cell		Input	Clock	Charging time	Load resistor	Initial load	Final load	Initial load	Final load
Test #	Type	Size	[V]	[Hz]	[Hour]	[Ω]	voltage	voltage	voltage	voltage
1	Rigid	4 cm^2	0.35	20	2	9.85K	0.804	0.659	0.759	0.612
2	Rigid	4 cm^2	0.4	20	2	9.85K	0.790*	0.648	0.804	0.659
3	Rigid	4 cm^2	0.45	20	2	9.85K	0.818	0.688	0.828	0.701
4	Flexible	4 cm^2	0.45	2	12	100.2	0.775	0.497	0.689	0.445

*Initial load voltage for Test 3 before charging is estimated value because of a slacken load connection.

[0092] As described above with respect to FIGS. **13-21**, a switched-capacitor DC-DC converter is implemented using a CMOS process for a battery cell charging application. Up to 40% energy transfer efficiency is obtained through capacitor charging tests. For battery cell charging tests, the functionality of the converter is verified for both rigid and flexible type battery cells using much smaller input voltage compared with general high charging voltage, more than 1.2V for the batteries discussed with respect to FIGS. **13-21**.

[0093] The techniques described above show a dramatic increase in power harvesting efficiency as compared to existing RF Power Harvesting designs and, enable recharging portable wireless electric using ambient RF energy sources. Utilizing these improvements, a design goal of generating 1V output voltage with a greater than 20% RF to DC conversion efficiency from RF energy levels measured in the environment (66 uW) was met. This represents better than double the RF to DC conversion efficiency of the related art power matched RF energy harvesting circuit based on a Villard voltage doubler.

[0094] Several design improvements, novel to RF power harvesting circuits, have been disclosed. These improvement include RF to DC conversion efficiency through a reduction in the body effect of diode connected MOSFETs, reduction in the threshold voltage and by reducing the affects of circuit parasitics. These circuit improvements have been simulated to show a better than 60% improvement to RF to DC conversion efficiency.

[0095] While the present invention has been particularly shown and described with reference to exemplary embodiments thereof, it will be understood by one of ordinary skill in the art that various changes in form and details may be made therein without departing from the spirit and scope of the present invention as defined by the following claims.

1. An RF power harvesting device comprising:
an inductor;
a first capacitor connected to the inductor;
a first MOSFET connected to a first node, and
a second MOSFET connected to the first node,
wherein the inductor or the first capacitor are connected to the first node.

2. The RF power harvesting device of claim **1**, wherein values of the first MOSFET and the second MOSFET are such that intrinsic capacitances of the first MOSFET and the second MOSFET and the inductor constitute a substantially resonant circuit during operation of the RF power harvesting device.

3. The RF power harvesting device of claim **1**, further comprising:
a second capacitor connected to a second node, and the second MOSFET is connected to the second node,
wherein the second MOSFET is a PMOSFET.

4. The RF power harvesting device of claim **1**, further comprising:
a receiver which detects and receives ambient RF energy,
wherein the first capacitor and the receiver are connected at a third node, the first capacitor and the inductor are connected in series at a fourth node, and the inductor is connected to the first node.

5. The RF power harvesting device of claim **1**, further comprising:
a first set of resisting elements connected to a first gate of the first MOSFET to apply a first DC bias to the first gate; and
a second set of resisting elements connected to a second gate of the second MOSFET to apply a second DC bias to the second gate.

6. A receiver comprising:
an impedance matching circuit connected to a first node;
a first MOSFET connected to the first node; and
a second MOSFET connected to the first node, wherein
the first MOSFET is a diode-connected p type MOSFET.

7. The receiver of claim **6**, wherein the impedance matching circuit comprises an inductor and a capacitor in series, the inductor connected to the first node.

8. The receiver of claim **6**, wherein a resistive biasing network provides a bias voltage to gate terminals of the first MOSFET and the second MOSFET.

9. A system comprising:
a receiver;
a voltage converter; and
an energy storage device, wherein
the receiver is configured to receive a high frequency signal and supply a first voltage to the voltage converter, and
the voltage converter is configured to amplify the first voltage supplied by the receiver and supply the amplified voltage to the energy storage device.

10. The system of claim **9**, wherein the voltage converter includes a switched capacitor circuit.

(57) **ABSTRACT**

Disclosed is an apparatus for an application including a core device for the application. The apparatus includes a power (preferably RF energy) harvester connected to the core device to power the core device. Also disclosed is a method for an application. The method includes the steps of converting RF energy into usable energy. There is the step of powering the core device with the usable energy.

POWERING DEVICES USING RF ENERGY HARVESTING

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to and is a continuation application of U.S. patent application Ser. No. 12/499,618, filed Jul. 8, 2009, which is a divisional application of U.S. patent application Ser. No. 11/447,412, filed Jun. 6, 2006, which claims priority to U.S. Provisional Patent Application No. 60/688,587, filed on Jun. 8, 2005; each of which is incorporated herein by reference in its entirety.

BACKGROUND

[0002] The present invention is related to the wireless powering of devices. More specifically, the present invention is related to the wireless powering of devices with a power harvester.

[0003] As processor capabilities have expanded and power requirements have decreased there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones, and wireless keyboards to building sensors and active RFID tags.

[0004] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily batteries as the key design parameter. While performance of processors and portable devices have been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not provide the lifetime cost and maintenance requirements for applications that require a large number of untethered devices such as logistics, and building automation. Today's devices that need two-way communication require scheduled maintenance every three to 18 months to replace or recharge the device's power source (typically a battery). One-way devices simply broadcasting their status (one-way) such as automated utility meter readers have a better battery life, typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and disruptive to the entire system that a device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0005] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the external environment. The harnessed energy would then either directly power an untethered device or augment a battery or other storage component. Directly powering an untethered device enables the device to be constructed without the need for a battery. Augmenting a storage component could be along two lines: 1) increasing the overall life of the device or 2) by providing more power to the device to increase the functionality of the device. The other parameters for an ideal solution is that the harnessing device could be used in a wide range of environments including harsh and sealed environments (e.g. nuclear reactors), would be inexpensive to produce, would be safe for humans, and would have a minimal effect on the basic size, weight and other physical characteristics of the untethered device.

SUMMARY

[0006] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises a power harvester (preferably a radio frequency (RF) energy harvester) connected to the core device to power the core device.

[0007] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises means for receiving energy wirelessly and providing power from the energy to the core device to power the integrated circuit of the core device. The receiving means is connected to the core device.

[0008] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit of the core device with the usable energy.

[0009] This invention pertains to a technique that uses radio frequency (RF) energy as a source of energy to directly power a device or augment a power storage component in a device. The present invention meets the requirements described in the previous "Background of the Invention" section.

[0010] Traditional RF receiving devices have focused on maximizing selectivity of the frequency to isolate and to be coherent without interference from other sources. In contrast, while the present invention operates at a specific frequency or range of frequencies, the device accepts any interference to supplement the output power of the device. Also, the research related to power harvesting that uses RF energy as a source has primarily focused on devices in close proximity of the source (inductive or near-field energy). In most cases, prior research assumed a dedicated or directed source of RF to power the device.

[0011] The invention should not be confused with power transfer by inductive coupling, which requires the device to be relatively close to the power transmission source. The RFID Handbook by the author Klaus Finkenzeller defines the inductive coupling region as distance between the transmitter and receiver of less than 0.16 times lambda where lambda is the wavelength of the RF wave. The invention can be implemented in the near field (sometimes referred to as inductive) region as well as the far-field region. The far-field region is distances greater than 0.16 times lambda.

[0012] It is an object of this invention to provide a method and apparatus to

- **[0013]** 1. remotely energize an untethered device without using direct wiring
- **[0014]** 2. power or augment the life of the power storage component so it matches the life of the device and, ultimately, powers the off-grid device with or without the use of batteries
- **[0015]** 3. allow untethered devices to be virtually maintenance free
- **[0016]** 4. provide augmentation for other energy harvesting technologies (solar, piezoelectric, etc.)
- **[0017]** 5. provide backup power to tethered devices

[0018] It is a further object of this invention to directly power a device or augment a power storage component in a device in conjunction with other power harvesting technologies and storage elements.

[0019] With this method and apparatus a device's power storage components do not require replacement, thus enabling the device to be permanently placed off-grid, where it may be physically impractical, costly, or dangerous (due to a harsh environment) to provide maintenance.

[0020] For devices on-grid (tethered) or with reliable power sources, RF power harvesting can be used as a backup in case the primary power source is lost.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] In the accompanying drawings, the preferred embodiment of the invention and preferred methods of practicing the invention are illustrated in which:

[0022] FIG. **1** is a block diagram of an RF Power Harvesting block used to directly supply power to Core Device Components.

[0023] FIG. **2** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0024] FIG. **3** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0025] FIG. **4** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0026] FIG. **5** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0027] FIG. **6** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0028] FIG. **7** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0029] FIG. **8** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block.

[0030] FIG. **9** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block and used to supply power to Core Device Components.

[0031] FIG. **10** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0032] FIG. **11** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0033] FIG. **12** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0034] FIG. **13** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0035] FIG. **14** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0036] FIG. **15** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0037] FIG. **16** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0038] FIG. **17** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0039] FIG. **18** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger.

[0040] FIG. **19** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and the RF Power Harvesting block in communication with a Power Storage block.

[0041] FIG. **20** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components.

[0042] FIG. **21** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components and the RF Power Harvesting block in communication with a Power Storage block.

[0043] FIG. **22** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0044] FIG. **23** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0045] FIG. **24** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0046] FIG. **25** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0047] FIG. **26** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0048] FIG. **27** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0049] FIG. **28** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and the RF Power Harvesting block supplying power to Core Device Components.

[0050] FIG. **29** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0051] FIG. **30** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0052] FIG. **31** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0053] FIG. **32** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power Core Device Components.

[0054] FIG. **33** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or

Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

DETAILED DESCRIPTION

[0112] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0113] There is shown an apparatus **10** for an application. The apparatus **10** comprises a core device **22** preferably having an integrated circuit **36** for the application. The apparatus **10** comprises a power harvester **20** connected to the core device **22** to power the core device **22**.

[0114] The apparatus **10** preferably includes an alternative power source **24** connected to the core device **22** to power the core device **22** in conjunction with the power harvester **20**. Preferably, the apparatus **10** includes a power regulator **26** and/or power storage circuit **28** connected to the power harvester **20**. The apparatus **10** preferably includes a power storage charger **30** connected to the power harvester **20**. Preferably, the apparatus **10** includes a power storage connected to the power harvester **20**.

[0115] Preferably, the core device **22** includes a memory **38** connected to the integrated circuit **36** and to the power harvester **20** to power the memory **36**.

[0116] The core device **22** can include a sensor **32**, as shown in FIG. **89**. The sensor **32** can include a proximity sensor, an intrusion sensor, an environmental sensor, a chemical sensor, a biological sensor, a sensor in contact with an automobile, an occupancy sensor, a motion sensor, a position sensor, a metal detector, or a sensor **32** in contact with an aircraft. The sensor **32** can include an alarm connected to the power harvester **20** to power the alarm, a display connected to the power harvester **20** to power the display, a sensor **32** disposed in a building, an industrial automation sensor, a sensor **32** in contact with an elevator, a temperature sensor, a fire sensor, or an accelerometer.

[0117] The sensor **32** can include a level sensor, a gas level sensor, a fluid level sensor, a light level sensor. The sensor **32** can include a flow sensor, a gas flow sensor, a fluid flow sensor, a light flow sensor, or a plasma flow sensor.

[0118] The sensor **32** can include a pressure sensor, a gas pressure sensor, a fluid pressure sensor, a light sensor, an infrared light sensor, an ultraviolet light sensor, an x-ray sensor, a cosmic ray sensor, a visible light sensor, a gamma ray sensor, a stress sensor, a strain sensor, a depth sensor, or an electrical characteristic sensor.

[0119] The sensor **32** includes a voltage sensor, a current sensor, a viscosity sensor, an acoustical sensor, a sound sensor, a listening sensor, a thickness sensor, a density sensor, a surface quality sensor, a volume sensor, a physical sensor, a mass sensor, a weight sensor, a conductivity sensor, a distance sensor, an orientation sensor, or a vibration sensor.

[0120] The sensor **32** can include a radioactivity sensor, a field strength sensor, an electric field sensor or a magnetic field sensor, a smoke detector, a carbon monoxide detector, a radon detector, an air quality sensor, a humidity sensor, a glass breakage sensor, or a break beam detector. The sensor can include a thermal energy sensor, an electromagnetic sensor, a mechanical sensor, an optical sensor, a radiation sensor, a sensor in contact with a vehicle, or a sensor **32** in contact with a water craft.

[0121] The present invention pertains to an apparatus **10** for an application. The apparatus **10** comprises a core device **22** having an integrated circuit **36** for the application. The apparatus **10** comprises means for receiving energy wirelessly and providing power from the energy to the core device **22** to power the integrated circuit **36** of the core device **22**. The receiving means is connected to the core device **22**. Preferably, the core device **22** includes means for sensing.

[0122] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit **36** of the core device **22** with the usable energy.

[0123] Preferably, there is the step of regulating the usable energy provided to the core device **22**. There is preferably the step of storing the usable energy. Preferably, there is the step of providing power to the core device **22** from an alternative power source **24** in conjunction with the usable energy.

[0124] Alternatively, the core device **22** can include a computer peripheral **34**, as shown in FIG. **90**. The computer peripheral **34** can include a handheld game, a gaming system, a game controller, a controller, a keyboard, a mouse, a computer terminal, computer storage, or computer equipment.

[0125] The present invention can be implemented in numerous ways. A number of these ways are depicted in FIGS. **1-90**. These figures contain multiple blocks that are configured in multiple ways.

[0126] In the figures, an arrow represents the flow of power unless otherwise stated. Single-headed (one-way) arrows represent that the power is flowing from one block to another. The single-headed arrow may represent multiple wires that provide power from one block to multiple parts in the other block. Two-headed (two-way) arrows represent a single wire that can have power flow in either direction or multiple wires each having power flow in a single direction.

[0127] As an example, a two-headed arrow between an RF power harvesting **20** block and a power regulation **26** and/or power storage circuit **28** block can represent a single wire that allows harvested power to flow into a storage device such as a capacitor. The same block diagram can also represent two wires between the two blocks with the first wire allowing harvested power to flow into a voltage regulator **26**. The second wire can allow the regulated voltage to feedback to the RF power harvesting **20** block to provide power to internal components such as transistors to increase the performance of the RF power harvesting **20** block.

[0128] Each block is described in detail below. Each block represents the functionality described below associated with it. For instance, the RF power harvesting **20** block describes a power harvester **20**, and the power regulation **26** and/or power storage circuit **28** block describes a power regulator **26** and a power storage circuit **28**.

Device's Power System Block

[0129] The device's power system block includes all components/circuitry required to power the device. This block may include an RF power harvesting **20** block, a power regulation **26** and/or power storage circuit **28** block, a power storage block, and/or a power storage charger **30** block (all discussed below).

RF Power Harvesting **20** Block

[0130] The RF power harvesting **20** block is connected to an antenna. The antenna may or may not be used as the communications antenna for the core device **22** components. The RF power harvesting **20** block is used to convert the energy captured by the antenna into usable power, such as direct current (DC) voltage.

[0131] This block may include antenna matching, rectifying circuitry, voltage transforming circuitry, and/or other performance optimizing circuitry. The rectifying circuitry may include a diode(s), a transistor(s), or some other rectifying device or combination. Examples of the rectifying circuitry include, but are not limited to, half-wave, full-wave, and voltage doubling circuits.

[0132] The output of the RF power harvesting **20** block is a DC voltage or current. The RF power harvesting **20** block may accept feedback (or input) from other circuitry or blocks, which may be used to control the harvesting circuitry to improve the performance or vary the output. This feedback may include, but is not limited to, a DC voltage or a clock from the core device **22** components.

[0133] U.S. Pat. No. 6,615,074 (FIGS. **8**, **9**, **12***a*, **12***b*, **13**, **14**), incorporated by reference, herein, shows numerous examples of RF power harvesting circuits that can be used to implement the block and function described.

Power Regulation **26** and/or Power Storage Circuit **28** Block

[0134] It may be necessary to regulate the converted power (i.e., hold the power at a constant level) for specific devices. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications.

[0135] The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or switching regulator **26** to hold the voltage at a constant level.

[0136] Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

[0137] This block may also include, with or without the regulation, a storage device such as a capacitor, a battery, or some other device able to store charge. The output from the power regulation **26** and/or power storage circuit **28** block may be used as feedback to other blocks within the device's power system block or to the alternative power sources **24** block (described below), if they require a regulated supply voltage or stored power.

[0138] U.S. Pat. No. 6,894,467 (FIGS. **1**, **3**), Linear Voltage Regulator, incorporated by reference, herein, is an example of a practical application of implementing the regulation described in the block. U.S. Pat. No. 6,297,618 (FIGS. **1-4**), Power storage device and method of measuring voltage of storage battery, incorporated by reference, herein, is an example of a practical application of implementing the storage described in the block.

Power Storage Charger **30** Block

[0139] The power storage charger **30** block may be needed if a power storage component of the device requires a special charging mechanism, such as pulse charging or trickle charging. This block controls how the captured and converted power is supplied to the power storage component.

[0140] U.S. Pat. No. 6,836,095 (FIGS. **1-3**), Battery Charging Method and Apparatus, incorporated by reference herein, is an example of a practical application of implementing the special charging mechanism described in the block.

Power Storage Block

[0141] If a device has intermittent power requirements, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block, which could include a battery, a capacitor, and/or another type of power storage component. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other power storage elements.

[0142] The output from the power storage block may be used as feedback to other blocks within the device's power system or to the alternative power sources **24** block, if they require a dedicated and predictable supply voltage.

[0143] U.S. Pat. No. 6,297,618 (FIGS. **1-4**), Power Storage Device and Method of Measuring Voltage of Storage Battery, incorporated by reference herein, is an example of a practical application of implementing the storage described in the block. U.S. Pat. No. 6,835,501, Alkaline Rechargeable Battery, incorporated by reference herein, is also an example of a practical application of implementing the storage described in the block.

Core Device **22** Components Block

[0144] The core device **22** components block is the portion of the device that is receiving power from the device's power system. This block may be, but is not limited to, the devices listed in the subsequent pages of this document. It may be advantageous for the core device **22** components block to communicate with any of the blocks that are supplying power to it. This communication can include, but is not limited to, a feedback control signal such as a clock or an ON/OFF command. As an example, the device may want to turn off the alternative power sources **24** block if it is receiving sufficient power from the RF power harvesting **20** block.

Alternative Power Sources **24** Block

[0145] RF energy harvesting also has the ability to be augmented by other types of power harvesting, storage components, or dedicated sources (e.g. power line). The alternative power sources **24** block shows how this type of system could be implemented. The augmenting power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. This block can work independently or have communication with other blocks.

[0146] U.S. Pat. No. 6,784,358, Solar Cell Structure Utilizing an Amorphous Silicon Discrete By-Pass Diode, incorporated by reference herein, is an example of a practical application of implementing an alternative power source **24** described by the block. U.S. Pat. No. 6,858,970, Multi-Frequency Piezoelectric Energy Harvester, incorporated by reference herein, is also an example of a practical application of implementing an alternative power source **24** described by the block.

Power Regulation **26**, Storage **28** and/or Storage Charging **30** Block

[0147] The power regulation **26**, storage **28** and/or storage charging **30** block contains all the combinations of the power regulation **26** and/or power storage circuit **28** block, power storage charger **30** block, and power storage block. This block is used in the later figures to reduce the number of figures needed to show how the blocks can interconnect.

[0148] The disclosed invention is an apparatus and method for an application for retrieving radio frequency (RF) energy by an antenna, converting that energy into direct current (DC) power, regulating that energy using an optimized circuit, storing that energy in an optimized component, and/or supplying the power for a specific device.

Retrieval of RF Energy

[0149] The RF energy is retrieved from the environment by the use of the antenna. The antenna can be shared or standalone with respect to an antenna used for the device's wireless communication. FIGS. **54-56** show a device that has an antenna A for use by the RF power harvester **20** and an antenna B used for wireless one-way or two-way communication. FIGS. **57-59** show a device where the antenna is shared by both a device's communication module (within the core device **22** components) and the RF power harvester **20**. In terms of form factor, the antenna used by the apparatus **10** can be a separate component or integrated directly into the form factor of the device.

[0150] The antenna is able to capture two types of available RF energy. The first type of energy exists as ambient RF energy. This type of RF surrounds us in our day-to-day lives and is usually generated to carry one way or two-way combinations of voice, video and data communications. The sources that the antenna can harvest from include, but are not limited to, medium-frequency AM radio broadcast, very-high-frequency (VHF) FM radio broadcast and television broadcast, ultra-high-frequency (UHF) broadcast, cellular base stations, wireless data access points, super-high-frequency (SHF) frequencies, and the industrial, scientific, and medical (ISM) bands. These sources cover transmission frequencies from 300 kHz to 30 GHz.

[0151] The second type of energy available is directed RF energy. This type of RF energy is directed from a transmitter specifically designed to deliver RF energy for harvesting by the antenna. The transmitter can be configured as a standalone device or integrated into an existing device.

Conversion of the Energy into DC

[0152] The RF energy captured by the antenna must be converted into a useful form of energy for the specific device. This conversion is shown in block form in all FIGS. (**1-90**) as the RF power harvesting **20** block. The most common form of useable energy is DC energy. To perform this conversion, the block includes circuitry to rectify the captured alternating current (AC) energy to create DC energy. The rectification in this block can be done with a diode(s), a transistor(s), or some other rectifying device or combination.

Regulation of the Energy

[0153] It may be necessary to regulate the converted power (hold the power at a constant level) for specific devices. FIGS. **2-7**, **10-17**, and **22-53** show how this regulation can be implemented using a power regulation **26** and/or power storage circuit **28** block. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications. The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or a switching regulator **26** to hold the voltage at a constant level. Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

Storage of the Energy

[0154] If a device has intermittent power requirements, such as the devices exampled by FIGS. **2-53**, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block or the power regulation **26** and/or power storage circuit **28** block. Storage devices can include, but are not limited to, a battery, a capacitor, or another type of power storage component. In certain applications, it may be necessary to include additional circuitry that controls how the power is transferred to the storage device. The power storage charger **30** block is shown in FIGS. **18-53**. This may be needed if the power storage component requires a special charging mechanism such as pulse charging or trickle charging. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. There are devices that will not require storage. These devices can run directly off of the converted power. These devices also may or may not require regulation of the captured power.

Supplying the Power

[0155] The captured DC power, which may or may not be regulated and/or stored, is supplied to the device, which is represented by the core device **22** components block in the figures. This may be a single connection or it may supply multiple parts of the device with power.

[0156] RF energy harvesting also has the ability to be augmented by other types of power harvesting or storage components. Other power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. FIGS. **60-88** show how the alternative power sources **24** block can be connected to an RF energy harvesting system. These figure show how the RF energy harvesting **20** block and the alternative power sources **24** block can work independently or have communication with each other. The antenna configurations shown in FIGS. **54-59** are still applicable with the addition of an alternative power sources **24** block. These antenna configurations can be applied to FIGS. **60-88**.

[0157] RF energy harvesting also has the ability to provide a backup to devices on-grid (tethered) or with reliable power sources, which can be used in case the primary power source is lost. As an example, it may be mandated by regulations that a sensor has auxiliary power in case the primary supply is lost. It could be possible to use a rechargeable battery that obtains its charge from the primary supply when in operation. However, if the primary supply is lost for a time greater than the life of the rechargeable battery, the specification of uninterrupted power is not met. RF energy could be used to supply power to the described device while the primary supply is not available. The primary supply could include, but is not limited to, an on-grid connection, a generator, a battery, or other reliable power supply.

[0158] RF energy harvesting with or without alternative source augmentation is applicable to provide electric power directly or indirectly to a range of electronic components contained in any specific electrical or electronic device and includes, but is not limited to:

[0159] Passive electronic components, active electronic components;

[0160] Resistors, fixed resistors, variable resistors, thermistors, thyristor, thermocouple;

[0161] Capacitors, Electrolytic Capacitors, Tantalum Capacitors, Ceramic Capacitors, Multilayer Ceramic Capacitors, Polystyrene Film Capacitors, Electric Double Layer Capacitors (Super Capacitors), Polyester Film Capacitors, Polypropylene Capacitors, Mica Capacitors, Metallized Polyester Film Capacitors, Variable Capacitors;

[0162] Diodes, Voltage regulation diodes, light-emitting diodes, organic light-emitting diodes, Variable capacitance diodes, Rectification diodes, Switching diodes, Regulation Diodes, Diode bridges, Schottky barrier diodes, tunnel diodes, PIN diodes, Zener diodes, Avalanche diodes, TVSs;

[0163] Integrated circuits, microcontroller unit (MCU), microprocessor unit (MPU), logic circuits, memory, printed circuits, circuit boards, printed wiring boards;

[0164] Transistors, MOSFETs, FETs, BJTs, JFETs, IGBTs, Relays, Antennas, semiconductors, conductors, inductors, relays, diacs, triacs, SCRs, MOVs;

[0165] Fuses, circuit breakers;

[0166] Batteries, Non-rechargeable batteries, rechargeable batteries, coin cell batteries, button cell batteries, alkaline batteries, lithium batteries, lithium ion batteries, lithium polymer batteries, NIMH batteries, NICAD batteries, Lead acid batteries, Zinc air batteries, Manganese Lithium batteries, Niobium Titanium Lithium batteries, Vanadium Pentoxide Lithium batteries, Carbon

Zinc batteries, Zinc Chloride batteries, Lithium Thionyl Chloride batteries, Manganese Dioxide batteries, Lithium Poly-Carbonmonofluoride batteries, Lithium Manganese Dioxide batteries, Lithium Chloride batteries, Lead Acid Calcium batteries, Lead Acid Tin batteries, Oxy Nickel batteries, Silver Oxide batteries, Magnesium batteries;

[0167] Inductors, Coils, High Frequency Coils, Toroidal Coils, Transformers, switches, chokes;

[0168] Motors, DC motors, stepper motor, AC motors, Fans;

[0169] Crystals, Oscillators, Clocks, Timers; and

[0170] Displays, LCDs, LED displays.

[0171] RF energy harvesting with or without alternative source augmentation is applicable across a range of markets and specific devices and includes but is not limited to:

[0172] Consumer electronics:

[0173] Electronic equipment, wired devices, battery powered devices, wireless communication devices, cell phones, telephones, phones, cordless phones, portable phones, Bluetooth devices, Bluetooth headsets, handsfree headsets, headsets, headphones, Wireless headsets, radios, AM/FM radios, shortwave radios, weather radios, Two-way radios, portable radio, lights, lanterns, portable lights, flashlights, nightlights, spotlights, search lights, calculators, graphing calculators, desk calculators, clocks, alarm clocks, wall clocks, desk clocks, travel clocks, watches, wristwatches, pocket watches, stop watches, timers, voice recorders, Dictaphones, laser pointers, power tools, cordless power tools, electronic razors, electric razors, handheld games, gaming systems, game controllers, wireless game controllers, remote controls, battery chargers, computers, portable computers, keyless entry, toys, toy guns, toy laser guns, games, microphones, musical instruments, musical effects processors, musical instrument tuners, metronomes, electronic chord charts, door openers, garage door openers, PDA, Cameras, Video recorders, Multimeter, electronic test equipment, hand-held electronics, portable electronics, wireless pens, sound generators, noise generators, language translators, electric toothbrushes, portable televisions, pagers, transceivers, toy vehicles, remote control vehicles, toy planes, remote control planes, pet containment systems, invisible fence pet sensors, memory backup, base station battery backups, appliance battery backups, uninterrupted power supplies, GPS devices, memory retention power supplies, metal detectors, stud finders, metal stud finders, stun guns, tazers, wearable devices, baby monitors, intercoms, doorbells, wireless doorbells, electronic office supplies, electronic staplers, radar jammers, radar detectors, digital scales, microfilm cassettes, video head testers, compasses, noise canceling headphones, air samplers, depth finders, barometers, weather measurement instruments, data transfer devices, automatic distress signaling unit, Wireless audio speakers, Satellite radios, Police scanners, Car navigation systems (GPS devices), Decorative lights, Christmas lights, garden lights, lawn lights, ornamental lights, porch lights;

[0174] Multi-media players: MP3, DVD, analog music players, CD players, tape players, digital music players, digital video players, minidisc; and

[0175] Computer: keyboards, mice, peripherals, computer equipment, electronic computers, computer storage, computer terminals;

[0176] Building/Industrial Automation:

[0177] Sensors: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity, glass breakage, break beam detector;

[0178] Controls: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity; and

[0179] Devices: Thermostats, light switches, door locks, smart-card door locks, lighting, emergency lighting, motion lighting, safety lighting, highway lighting, construction lighting, sign lighting, roadway sign lighting, construction sign lighting, automatic flushing units, automatic soap dispenser, automatic paper towel dispenser, automatic faucets, automatic door sensors, identification reader, fingerprint reader, credit card readers, card readers, valve actuators, gauges, analog gauges, digital gauges, fire extinguishers, wireless switches, remotely operated inspection equipment, gas/oil pipeline monitoring systems, robotic pipeline inspection gauges, “auto-reclosers” for electric power lines, sonar buoys, telemetry systems, electronic record tracking systems, robbery tracking devices, interrogators, programmers, emergency exit alarms, alarms, flood alarms, gas alarms, electronic entry systems, security keypads, silo transducers, data recorders, signal tracers, antistatic strap testers, radiosonde weather balloons, utilities load controllers, profilometers, noise cancellation equipment, infrared beacons;

[0180] Military/Government:

[0181] Tracking tags: Weapons, vehicle, soldier, gear/assets, staff, general population, security access badges;

[0182] Sensors: Proximity, intrusion, environmental, chemical/biological; and

[0183] Equipment: Battery charger, surveillance, card readers, identification reader, fingerprint reader, retinal scanners, satellites, rockets, space vehicles, search and rescue transponders (SARTs), emergency position-indicating rescue beacons (EPIRBs), emergency locator transmitters (ELTs), military radios, electronic toll collection systems, postal tracking systems, communica-

tions, thermal imaging, night vision, training targets, field medical equipment, house arrest monitors, laser tags, electronic parking meters, multiple integrated laser engagement system, munitions and mines, ship sensors;

[0184] Utility:

- **[0185]** Gas consumption meters, water consumption meters, and electric consumption meters;

[0186] Logistics & Supply Chain Management:

- **[0187]** Radio-frequency identification devices (RFID), RFID readers;
- **[0188]** Tracking: Asset tags, cargo container location beacons, transponders, transceivers; and
- **[0189]** Devices: Smart price tags, smart shelving, handheld barcode scanner, barcode scanners, credit card readers, card readers, retail signage, hotel door locks;

[0190] Homeland Security:

- **[0191]** Sensors: Occupancy, proximity, environmental, chemical/biological, motion, position; and
- **[0192]** Metal detector wand;

[0193] Medical:

- **[0194]** Implantable: cochlear implants, neural stimulators, pace makers, medication administration, defibrillator;
- **[0195]** Body function monitors: pressure, temperature, respiration, blood oxygenation, insulin, hearing aid, pulse, EKG, heart, Holter;
- **[0196]** Tracking tags: Patient, baby identification, assets, supplies, staff, medication, instruments;
- **[0197]** Devices: Home healthcare equipment, ambulatory infusion pumps, blood analyzers, biofeedback systems, bone growth stimulators, thermometers, digital thermometers, stimulators, galvanic stimulators, muscle stimulators, pediatric scales; and

[0198] Agriculture—livestock tracking and asset tracking:

- **[0199]** Tracking: livestock, asset, wildlife tracking devices; and
- **[0200]** Equipment: cattle prods;

[0201] Automotive:

- **[0202]** Automotive antennas, Automotive Audio Systems, Automotive Lighting, Automotive Video Systems, Computers, Processors, Controls, Switches, Electric Motors, Actuators, Ignition Systems, Starter Systems, Injection Systems, Powertrain Electronics, Radar Detectors, Proximity Detectors, Safety Systems, Security Systems, Sensors, Regulators, Distributors, Vehicle Control, Wiper Systems, Washer Systems, Radio, Video Systems, Entertainment Systems, Navigation Systems, GPS systems, Power Mirror Systems, Emission control systems;

[0203] Appliances:

- **[0204]** Monitoring systems and control systems for major and small appliances including washing machines, dryers, refrigerators, freezers, coolers, air conditioners, humidifiers, dehumidifiers, air purifiers, air filters, fans, furnaces, water heaters, boilers, space heaters, sowing machines, ice makers, microwave ovens, convection ovens, ovens, toaster ovens, ranges, range hoods, cooktops, stoves, stovetops, crock pots, hot plates, dishwashers, garbage disposals, can openers, vacuum cleaners, blenders, mixers, food processors, irons, coffee makers, toasters, grills, hair dryers, electric tooth brushes, electric razors, electric drills, electric screwdrivers, chainsaws, lawnmowers, push mowers, riding mowers, trimmers, brush cutters, pruners, edgers, vending machines;

[0205] Ventilation, Heating, Air-Conditioning, and Commercial Refrigeration Equipment:

- **[0206]** Monitoring systems, control systems;

[0207] Engine, Turbine, and Power Transmission Equipment;

[0208] Monitoring systems, control systems;

[0209] Other General Purpose Machinery Manufacturing:

- **[0210]** Monitoring systems, control systems;

[0211] Telecommunications:

- **[0212]** Monitoring systems, control systems;
- **[0213]** Portable;

[0214] Aircraft:

- **[0215]** Monitoring systems, control systems, actuator systems, sensors.

[0216] It should be noted that devices within a specific category may be applicable across multiple areas even if they are not specifically listed. (e.g., temperature sensors apply to Industrial and Building Automation and Appliances).

[0217] To retrofit or redesign the devices listed, it is possible to implement the described systems in numerous ways. It may be advantageous to leave the device design as-is including the existing power supply. As an example, a device may use non-rechargeable batteries to operate. The device will most likely have a protection circuit to prevent damage if the batteries are installed incorrectly. The protection mechanism is commonly a diode inline with the positive terminal of the battery. In this case, the RF power harvester **20** with or without the alternative power source **24** could be inserted, with an antenna, into the device. The power generated by the RF power harvester **20** (and the alternative power source **24**, if applicable) could be connected to the device after the protection mechanism described to avoid potential charging of a non-rechargeable battery.

[0218] Another way to configure the device's power system is to replace the non-rechargeable batteries with rechargeable batteries. In this instance, the output from the RF power harvester **20** (and alternative power source **24**) could be connected to either side of the protections device. If the connection is before the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will recharge the battery and supply power to the device. If the connection is after the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will supply power to the device and the battery will supply any extra power needed that could not be supplied by the RF power harvester **20** (and the alternative power source **24**, if applicable). It should be noted that the protection device in this case is not needed for proper operation. Its only function would be to protect the batteries from being installed incorrectly. An antenna could be contained inside or placed on the outside of the device.

[0219] Another configuration of the device's power system is to remove the existing batteries and install the RF power harvester **20** (and the alternative power source **24**) in the enclosure provided for the batteries. An antenna could be contained inside or placed on the outside of the device.

[0220] Yet another method of configuring the device's power system would be to reduce the number of batteries and replace them with the RF power harvester **20** (and the alternative power source **24**). In this case, the output from the system would be connected to the batteries in series or par-

allel depending on the original battery configuration. An antenna could be contained inside or placed on the outside of the device.

[0221] An additional option, would be to completely redesign the product and integrate the required circuitry and storage components into the device. This method is probably the most advantageous because it can fully take advantage of the benefits offered by the RF power harvester **20** (and the alternative power source **24**). An antenna could be contained inside or placed on the outside of the device.

[0222] If the RF power harvester **20** (and the alternative power source **24**) is used as a backup to the primary power supply, a switch could be implemented into the system in order to switch the RF power harvester **20** (and the alternative power source **24**) on when the primary source is lost. In this case, an antenna could be contained inside or placed on the outside of the device.

[0223] To show the flexibility of RF energy harvesting, several products were retrofitted to include an RF power harvester **20** (energy harvesting circuitry). These products include a wireless keyboard, a wall clock, and a desk calculator.

[0224] The wireless keyboard is an example of recharging and augmenting a battery to supply power to a device. This system is shown in FIG. **13**. The output from the regulation circuitry recharges the battery and supplies power to the keyboard. The battery is also used to supply power to the keyboard. The keyboard also includes a separate antenna for receiving power and for data communications. The antenna configuration can be seen in FIG. **55**.

[0225] The wall clock is an example of a direct powering system. The wall clock was retrofitted to include an RF power harvester **20** and the internal AA battery was removed. This system is shown in FIG. **2**. The wall clock did not need regulation, but did require a capacitor for storage to supply the pulse of power to move the second hand.

[0226] The calculator is an example of using RF energy harvesting with another energy harvesting technology. The calculator had an internal 1.5V coin cell battery and a small solar panel. The internal battery was removed, however, the solar panel was left intact. This system is shown in FIG. **60**. In this system, the calculator can receive power from both the solar panel and the RF power harvester **20** to eliminate the need for a battery.

[0227] As an additional example, an RF power harvester **20** (energy harvesting circuit) similar to the ones shown in U.S. Pat. No. 6,615,074 (FIGS. **8**, **9**, **12***a*, **12***b*, **13**, **14**), was connected in series with a 0.5V solar cell. Individually, the solar cell was able to provide 0.480V to a 10 kilo-ohm resistor, which was being used to simulate the core device **22** components. This corresponds to 23 microwatts. The RF power harvesting circuit by itself was able to provide 2.093V across the 10 kilo-ohm resistor when being supplied by 1 milliwatt of RF power. This corresponds to 438 microwatts. The two circuit outputs were then combined in series by connecting the output from the RF energy harvesting circuit to the ground of the solar cell. The output of the solar cell was then connected to the resistor. The other end of the resistor was connected to the ground of the RF energy harvesting circuit. The voltage across the resistor with the circuits connected as shown in FIG. **63** was 2.445V. This corresponds to 598 microwatts.

[0228] As can be seen, the combination of the two technologies produces a result higher than the addition of the individual powers. From this, it can be determined that the two technologies can cooperate in a way that produces favorable results.

[0229] In the example given, the solar cell produces current to supply the load and helps to bias the RF rectifying diodes, which allows the RF energy harvesting circuit to operate a higher efficiency. The solar cell also changes the impedance seen by the RF energy harvesting circuit, which produces a beneficial result. To be more specific, when examining the power output of the individual circuit (solar and RF power harvesting), the sum of the power captured by the individual circuits was 23 μW+438 μW=461 μW. However, when the two circuits are combined and are allowed to work in conjunction with one another, the output power becomes 598 μW. This result shows that combining the two power-harvesting technologies produces a 30 percent increase in the output power for this example. This same technique can be applied to multiple energy harvesting technologies to produce even greater output power. The equations for this example are shown below.

[0230] Individual Circuits

$$P_I=P_1+P_2+\ldots+P_N$$

[0231] Combined Circuits

$$P_C>P_I=P_1+P_2+\ldots+P_N$$

[0232] where P_I is the sum of the individual output powers

[0233] P_C is the output of the combined circuit

[0234] P_1 is the output power from the first power harvesting technology

[0235] P_2 is the output power from the second power harvesting technology

[0236] P_N is the output power from the N^{th} power harvesting technology

[0237] N is the number of power harvesting technologies or circuits.

[0238] As can be seen by the previous examples, RF energy harvesting can be used alone or in conjunction with alternative power sources to power a wide range of devices. The addition of RF energy harvesting technology to the device allows for increased battery life, increased functionality, or the removal of the primary battery.

[0239] Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

What is claimed is:

1. An apparatus, comprising:

a first antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a second antenna different from and electrically isolated from the first antenna, the second antenna configured to wirelessly communicate with the source;

a power harvester electrically coupled to the first antenna and configured to convert the energy received at the first antenna to a DC voltage;

a radio-frequency identification (RFID) device electrically coupled to the power harvester and to the second antenna, the RFID device configured to wirelessly communicate with the source via the second antenna;

an integrated circuit configured to operate based on the DC voltage; and a sensor electrically coupled to the integrated circuit, the sensor configured to operate based on the DC voltage and to detect at least one of an environmental condition associated with a location of the apparatus or a physical condition associated with an item coupled to the apparatus.

2. The apparatus of claim **1**, further comprising:

a regulator coupled to the power harvester and configured to regulate the DC voltage to produce a regulated DC voltage, the sensor configured to operate based on the regulated DC voltage received from the regulator.

3. The apparatus of claim **1**, wherein the integrated circuit is configured to perform an application associated with the at least one of the environmental condition or the physical condition detected by the sensor.

4. The apparatus of claim **1**, further comprising:

an electronic display configured to operate based on the DC voltage.

5. The apparatus of claim **1**, wherein the sensor includes at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, an orientation sensor, or a position sensor.

6. The apparatus of claim **1**, wherein the RFID device does not operate based on a battery, and the sensor does not operate based on a battery.

7. The apparatus of claim **1**, wherein the apparatus is a RFID tag.

8. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage;

a radio-frequency identification (RFID) device electrically coupled to the antenna and configured to wirelessly communicate with the source via the antenna, the RFID device operatively coupled to the power harvester and including an integrated circuit configured to operate based on the DC voltage; and

a sensor electrically coupled to the RFID device and the power harvester, the sensor configured to operate based on the DC voltage and to detect at least one of an environmental condition associated with a location of the apparatus or a physical condition associated with an item coupled to the apparatus,

the integrated circuit configured to perform an application associated with the at least one of the environmental condition or the physical condition detected by the sensor.

9. The apparatus of claim **8**, wherein the power harvester is configured to wirelessly communicate with the source via the antenna.

10. The apparatus of claim **8**, wherein the sensor is electrically coupled to the antenna and is configured to wirelessly communicate with the source via the antenna.

11. The apparatus of claim **8**, further comprising:

a regulator coupled to the power harvester and configured to regulate the DC voltage to produce a regulated DC voltage, the integrated circuit configured to operate based on the regulated DC voltage received from the regulator.

12. The apparatus of claim **8**, further comprising:

an electronic display configured to operate based on the DC voltage.

13. The apparatus of claim **8**, wherein the sensor includes at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, or a position sensor.

14. The apparatus of claim **8**, wherein the RFID device does not operate based on a battery, and the sensor does not operate based on a battery.

15. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage to produce a power associated with the DC voltage;

a regulator coupled to the power harvester and configured to regulate the power associated with the DC voltage to produce a regulated power;

a radio-frequency identification (RFID) device electrically coupled to the antenna and configured to wirelessly communicate with the source via the antenna, the RFID device electrically coupled to the power harvester and the regulator, the RFID device including an integrated circuit configured to operate based on at least one of the power received from the power harvester or the regulated power received from the regulator; and

an electronic display electrically coupled to the RFID device and configured to operate, at least in part, based on the regulated power received from the regulator.

16. The apparatus of claim **15**, wherein the electronic display is electrically coupled to the regulator, the electronic display is configured to operate based on the regulated power received from the regulator and the power received from the power harvester.

17. The apparatus of claim **15**, wherein the electronic display is one of a liquid-crystal display (LCD) or a light-emitting diode (LED) display.

18. The apparatus of claim **15**, further comprising:

a sensor configured to operate, at least in part, based on the regulated power received from the regulator, the sensor including at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, or a position sensor.

19. The apparatus of claim **15**, wherein the power harvester is configured to wirelessly communicate with the source via the antenna.

20. The apparatus of claim **15**, wherein the RFID device does not operate based on a battery, and the electronic display does not operate based on a battery.

(57) **ABSTRACT**

Disclosed is an apparatus for an application including a core device for the application. The apparatus includes a power (preferably RF energy) harvester connected to the core device to power the core device. Also disclosed is a method for an application. The method includes the steps of converting RF energy into usable energy. There is the step of powering the core device with the usable energy.

POWERING DEVICES USING RF ENERGY HARVESTING

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to and is a continuation application of U.S. patent application Ser. No. 14/143,334, filed Dec. 30, 2013, which claims priority to and is a continuation application of U.S. patent application Ser. No. 12/499,618, filed Jul. 8, 2009 (now U.S. Pat. No. 8,621,245), which is a divisional application of U.S. patent application Ser. No. 11/447,412, filed Jun. 6, 2006, which claims priority to U.S. Provisional Patent Application No. 60/688,587, filed on Jun. 8, 2005; each of which is incorporated herein by reference in its entirety.

BACKGROUND

[0002] The present invention is related to the wireless powering of devices. More specifically, the present invention is related to the wireless powering of devices with a power harvester.

[0003] As processor capabilities have expanded and power requirements have decreased there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones, and wireless keyboards to building sensors and active RFID tags.

[0004] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily batteries as the key design parameter. While performance of processors and portable devices have been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not provide the lifetime cost and maintenance requirements for applications that require a large number of untethered devices such as logistics, and building automation. Today's devices that need two-way communication require scheduled maintenance every three to 18 months to replace or recharge the device's power source (typically a battery). One-way devices simply broadcasting their status (one-way) such as automated utility meter readers have a better battery life, typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and disruptive to the entire system that a device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0005] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the external environment. The harnessed energy would then either directly power an untethered device or augment a battery or other storage component. Directly powering an untethered device enables the device to be constructed without the need for a battery. Augmenting a storage component could be along two lines: 1) increasing the overall life of the device or 2) by providing more power to the device to increase the functionality of the device. The other parameters for an ideal solution is that the harnessing device could be used in a wide range of environments including harsh and sealed environments (e.g. nuclear reactors), would be inexpensive to produce, would be safe for humans, and would have a minimal effect on the basic size, weight and other physical characteristics of the untethered device.

SUMMARY

[0006] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises a power harvester (preferably a radio frequency (RF) energy harvester) connected to the core device to power the core device.

[0007] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises means for receiving energy wirelessly and providing power from the energy to the core device to power the integrated circuit of the core device. The receiving means is connected to the core device.

[0008] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit of the core device with the usable energy.

[0009] This invention pertains to a technique that uses radio frequency (RF) energy as a source of energy to directly power a device or augment a power storage component in a device. The present invention meets the requirements described in the previous "Background of the Invention" section.

[0010] Traditional RF receiving devices have focused on maximizing selectivity of the frequency to isolate and to be coherent without interference from other sources. In contrast, while the present invention operates at a specific frequency or range of frequencies, the device accepts any interference to supplement the output power of the device. Also, the research related to power harvesting that uses RF energy as a source has primarily focused on devices in close proximity of the source (inductive or near-field energy). In most cases, prior research assumed a dedicated or directed source of RF to power the device.

[0011] The invention should not be confused with power transfer by inductive coupling, which requires the device to be relatively close to the power transmission source. The RFID Handbook by the author Klaus Finkenzeller defines the inductive coupling region as distance between the transmitter and receiver of less than 0.16 times lambda where lambda is the wavelength of the RF wave. The invention can be implemented in the near field (sometimes referred to as inductive) region as well as the far-field region. The far-field region is distances greater than 0.16 times lambda.

[0012] It is an object of this invention to provide a method and apparatus to

[0013] 1. remotely energize an untethered device without using direct wiring

[0014] 2. power or augment the life of the power storage component so it matches the life of the device and, ultimately, powers the off-grid device with or without the use of batteries

[0015] 3. allow untethered devices to be virtually maintenance free

[0016] 4. provide augmentation for other energy harvesting technologies (solar, piezoelectric, etc.)

[0017] 5. provide backup power to tethered devices

[0018] It is a further object of this invention to directly power a device or augment a power storage component in a device in conjunction with other power harvesting technologies and storage elements.

[0019] With this method and apparatus a device's power storage components do not require replacement, thus enabling the device to be permanently placed off-grid, where it may be physically impractical, costly, or dangerous (due to a harsh environment) to provide maintenance.

[0020] For devices on-grid (tethered) or with reliable power sources, RF power harvesting can be used as a backup in case the primary power source is lost.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] In the accompanying drawings, the preferred embodiment of the invention and preferred methods of practicing the invention are illustrated in which:

[0022] FIG. **1** is a block diagram of an RF Power Harvesting block used to directly supply power to Core Device Components.

[0023] FIG. **2** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0024] FIG. **3** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0025] FIG. **4** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0026] FIG. **5** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0027] FIG. **6** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0028] FIG. **7** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0029] FIG. **8** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block.

[0030] FIG. **9** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block and used to supply power to Core Device Components.

[0031] FIG. **10** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0032] FIG. **11** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0033] FIG. **12** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0034] FIG. **13** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0035] FIG. **14** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0036] FIG. **15** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0037] FIG. **16** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0038] FIG. **17** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0039] FIG. **18** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger.

[0040] FIG. **19** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and the RF Power Harvesting block in communication with a Power Storage block.

[0041] FIG. **20** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components.

[0042] FIG. **21** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components and the RF Power Harvesting block in communication with a Power Storage block.

[0043] FIG. **22** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0044] FIG. **23** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0045] FIG. **24** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0046] FIG. **25** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0047] FIG. **26** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0048] FIG. **27** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0049] FIG. **28** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and the RF Power Harvesting block supplying power to Core Device Components.

[0050] FIG. **29** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0051] FIG. **30** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0052] FIG. **31** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0053] FIG. **32** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power Core Device Components.

[0054] FIG. **33** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or

Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0055] FIG. **34** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0056] FIG. **35** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0057] FIG. **36** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0058] FIG. **37** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0059] FIG. **38** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0060] FIG. **39** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0061] FIG. **40** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to the Power Storage Charger.

[0062] FIG. **41** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0063] FIG. **42** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0064] FIG. **43** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to a Power Storage Charger.

[0065] FIG. **44** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and the RF Power Harvesting block supplying power to Core Device Components and used to supply power to a Power Storage Charger.

[0066] FIG. **45** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0067] FIG. **46** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0068] FIG. **47** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to a Power Storage Charger.

[0069] FIG. **48** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power Core Device Components and used to supply power to a Power Storage Charger.

[0070] FIG. **49** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

DETAILED DESCRIPTION

[0112] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0113] There is shown an apparatus **10** for an application. The apparatus **10** comprises a core device **22** preferably having an integrated circuit **36** for the application. The apparatus **10** comprises a power harvester **20** connected to the core device **22** to power the core device **22**.

[0114] The apparatus **10** preferably includes an alternative power source **24** connected to the core device **22** to power the core device **22** in conjunction with the power harvester **20**. Preferably, the apparatus **10** includes a power regulator **26** and/or power storage circuit **28** connected to the power harvester **20**. The apparatus **10** preferably includes a power storage charger **30** connected to the power harvester **20**. Preferably, the apparatus **10** includes a power storage connected to the power harvester **20**.

[0115] Preferably, the core device **22** includes a memory **38** connected to the integrated circuit **36** and to the power harvester **20** to power the memory **36**.

[0116] The core device **22** can include a sensor **32**, as shown in FIG. **89**. The sensor **32** can include a proximity sensor, an intrusion sensor, an environmental sensor, a chemical sensor, a biological sensor, a sensor in contact with an automobile, an occupancy sensor, a motion sensor, a position sensor, a metal detector, or a sensor **32** in contact with an aircraft. The sensor **32** can include an alarm connected to the power harvester **20** to power the alarm, a display connected to the power harvester **20** to power the display, a sensor **32** disposed in a building, an industrial automation sensor, a sensor **32** in contact with an elevator, a temperature sensor, a fire sensor, or an accelerometer.

[0117] The sensor **32** can include a level sensor, a gas level sensor, a fluid level sensor, a light level sensor. The sensor **32** can include a flow sensor, a gas flow sensor, a fluid flow sensor, a light flow sensor, or a plasma flow sensor.

[0118] The sensor **32** can include a pressure sensor, a gas pressure sensor, a fluid pressure sensor, a light sensor, an infrared light sensor, an ultraviolet light sensor, an x-ray sensor, a cosmic ray sensor, a visible light sensor, a gamma ray sensor, a stress sensor, a strain sensor, a depth sensor, or an electrical characteristic sensor.

[0119] The sensor **32** includes a voltage sensor, a current sensor, a viscosity sensor, an acoustical sensor, a sound sensor, a listening sensor, a thickness sensor, a density sensor, a surface quality sensor, a volume sensor, a physical sensor, a mass sensor, a weight sensor, a conductivity sensor, a distance sensor, an orientation sensor, or a vibration sensor.

[0120] The sensor **32** can include a radioactivity sensor, a field strength sensor, an electric field sensor or a magnetic field sensor, a smoke detector, a carbon monoxide detector, a radon detector, an air quality sensor, a humidity sensor, a glass breakage sensor, or a break beam detector. The sensor can include a thermal energy sensor, an electromagnetic sensor, a mechanical sensor, an optical sensor, a radiation sensor, a sensor in contact with a vehicle, or a sensor **32** in contact with a water craft.

[0121] The present invention pertains to an apparatus **10** for an application. The apparatus **10** comprises a core device **22** having an integrated circuit **36** for the application. The apparatus **10** comprises means for receiving energy wirelessly and providing power from the energy to the core device **22** to power the integrated circuit **36** of the core device **22**. The receiving means is connected to the core device **22**. Preferably, the core device **22** includes means for sensing.

[0122] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit **36** of the core device **22** with the usable energy.

[0123] Preferably, there is the step of regulating the usable energy provided to the core device **22**. There is preferably the step of storing the usable energy. Preferably, there is the step of providing power to the core device **22** from an alternative power source **24** in conjunction with the usable energy.

[0124] Alternatively, the core device **22** can include a computer peripheral **34**, as shown in FIG. **90**. The computer peripheral **34** can include a handheld game, a gaming system, a game controller, a controller, a keyboard, a mouse, a computer terminal, computer storage, or computer equipment.

[0125] The present invention can be implemented in numerous ways. A number of these ways are depicted in FIGS. **1-90**. These figures contain multiple blocks that are configured in multiple ways.

[0126] In the figures, an arrow represents the flow of power unless otherwise stated. Single-headed (one-way) arrows represent that the power is flowing from one block to another. The single-headed arrow may represent multiple wires that provide power from one block to multiple parts in the other block. Two-headed (two-way) arrows represent a single wire that can have power flow in either direction or multiple wires each having power flow in a single direction.

[0127] As an example, a two-headed arrow between an RF power harvesting **20** block and a power regulation **26** and/or power storage circuit **28** block can represent a single wire that allows harvested power to flow into a storage device such as a capacitor. The same block diagram can also represent two wires between the two blocks with the first wire allowing harvested power to flow into a voltage regulator **26**. The second wire can allow the regulated voltage to feedback to the RF power harvesting **20** block to provide power to internal components such as transistors to increase the performance of the RF power harvesting **20** block.

[0128] Each block is described in detail below. Each block represents the functionality described below associated with it. For instance, the RF power harvesting **20** block describes a power harvester **20**, and the power regulation **26** and/or power storage circuit **28** block describes a power regulator **26** and a power storage circuit **28**.

Device's Power System Block

[0129] The device's power system block includes all components/circuitry required to power the device. This block may include an RF power harvesting **20** block, a power regulation **26** and/or power storage circuit **28** block, a power storage block, and/or a power storage charger **30** block (all discussed below).

RF Power Harvesting **20** Block

[0130] The RF power harvesting **20** block is connected to an antenna. The antenna may or may not be used as the communications antenna for the core device **22** components. The RF power harvesting **20** block is used to convert the energy captured by the antenna into usable power, such as direct current (DC) voltage.

[0131] This block may include antenna matching, rectifying circuitry, voltage transforming circuitry, and/or other performance optimizing circuitry. The rectifying circuitry may include a diode(s), a transistor(s), or some other rectifying device or combination. Examples of the rectifying circuitry include, but are not limited to, half-wave, full-wave, and voltage doubling circuits.

[0132] The output of the RF power harvesting **20** block is a DC voltage or current. The RF power harvesting **20** block may accept feedback (or input) from other circuitry or blocks, which may be used to control the harvesting circuitry to improve the performance or vary the output. This feedback may include, but is not limited to, a DC voltage or a clock from the core device **22** components.

[0133] U.S. Pat. No. 6,615,074 (FIGS. 8, 9, 12*a*, 12*b*, 13, 14), incorporated by reference, herein, shows numerous examples of RF power harvesting circuits that can be used to implement the block and function described.

Power Regulation **26** and/or Power Storage Circuit **28** Block

[0134] It may be necessary to regulate the converted power (i.e., hold the power at a constant level) for specific devices. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications.

[0135] The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or switching regulator **26** to hold the voltage at a constant level.

[0136] Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

[0137] This block may also include, with or without the regulation, a storage device such as a capacitor, a battery, or some other device able to store charge. The output from the power regulation **26** and/or power storage circuit **28** block may be used as feedback to other blocks within the device's power system block or to the alternative power sources **24** block (described below), if they require a regulated supply voltage or stored power.

[0138] U.S. Pat. No. 6,894,467 (FIGS. 1, 3), Linear Voltage Regulator, incorporated by reference, herein, is an example of a practical application of implementing the regulation described in the block. U.S. Pat. No. 6,297,618 (FIGS. 1-4), Power storage device and method of measuring voltage of storage battery, incorporated by reference, herein, is an example of a practical application of implementing the storage described in the block.

Power Storage Charger **30** Block

[0139] The power storage charger **30** block may be needed if a power storage component of the device requires a special charging mechanism, such as pulse charging or trickle charging. This block controls how the captured and converted power is supplied to the power storage component.

[0140] U.S. Pat. No. 6,836,095 (FIGS. 1-3), Battery Charging Method and Apparatus, incorporated by reference herein, is an example of a practical application of implementing the special charging mechanism described in the block.

Power Storage Block

[0141] If a device has intermittent power requirements, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block, which could include a battery, a capacitor, and/or another type of power storage component. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other power storage elements.

[0142] The output from the power storage block may be used as feedback to other blocks within the device's power system or to the alternative power sources **24** block, if they require a dedicated and predictable supply voltage.

[0143] U.S. Pat. No. 6,297,618 (FIGS. 1-4), Power Storage Device and Method of Measuring Voltage of Storage Battery, incorporated by reference herein, is an example of a practical application of implementing the storage described in the block. U.S. Pat. No. 6,835,501, Alkaline Rechargeable Battery, incorporated by reference herein, is also an example of a practical application of implementing the storage described in the block.

Core Device **22** Components Block

[0144] The core device **22** components block is the portion of the device that is receiving power from the device's power system. This block may be, but is not limited to, the devices listed in the subsequent pages of this document. It may be advantageous for the core device **22** components block to communicate with any of the blocks that are supplying power to it. This communication can include, but is not limited to, a feedback control signal such as a clock or an ON/OFF command. As an example, the device may want to turn off the alternative power sources **24** block if it is receiving sufficient power from the RF power harvesting **20** block.

Alternative Power Sources **24** Block

[0145] RF energy harvesting also has the ability to be augmented by other types of power harvesting, storage components, or dedicated sources (e.g. power line). The alternative power sources **24** block shows how this type of system could be implemented. The augmenting power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. This block can work independently or have communication with other blocks.

[0146] U.S. Pat. No. 6,784,358, Solar Cell Structure Utilizing an Amorphous Silicon Discrete By-Pass Diode, incorporated by reference herein, is an example of a practical application of implementing an alternative power source **24** described by the block. U.S. Pat. No. 6,858,970, Multi-Frequency Piezoelectric Energy Harvester, incorporated by reference herein, is also an example of a practical application of implementing an alternative power source **24** described by the block.

Power Regulation **26**, Storage **28** and/or Storage Charging **30** Block

[0147] The power regulation **26**, storage **28** and/or storage charging **30** block contains all the combinations of the power regulation **26** and/or power storage circuit **28** block, power storage charger **30** block, and power storage block. This block is used in the later figures to reduce the number of figures needed to show how the blocks can interconnect.

[0148] The disclosed invention is an apparatus and method for an application for retrieving radio frequency (RF) energy by an antenna, converting that energy into direct current (DC) power, regulating that energy using an optimized circuit, storing that energy in an optimized component, and/or supplying the power for a specific device.

Retrieval of RF Energy

[0149] The RF energy is retrieved from the environment by the use of the antenna. The antenna can be shared or standalone with respect to an antenna used for the device's wireless communication. FIGS. **54-56** show a device that has an antenna A for use by the RF power harvester **20** and an antenna B used for wireless one-way or two-way communication. FIGS. **57-59** show a device where the antenna is shared by both a device's communication module (within the core device **22** components) and the RF power harvester **20**. In terms of form factor, the antenna used by the apparatus **10** can be a separate component or integrated directly into the form factor of the device.

[0150] The antenna is able to capture two types of available RF energy. The first type of energy exists as ambient RF energy. This type of RF surrounds us in our day-to-day lives and is usually generated to carry one way or two-way combinations of voice, video and data communications. The sources that the antenna can harvest from include, but are not limited to, medium-frequency AM radio broadcast, very-high-frequency (VHF) FM radio broadcast and television broadcast, ultra-high-frequency (UHF) broadcast, cellular base stations, wireless data access points, super-high-frequency (SHF) frequencies, and the industrial, scientific, and medical (ISM) bands. These sources cover transmission frequencies from 300 kHz to 30 GHz.

[0151] The second type of energy available is directed RF energy. This type of RF energy is directed from a transmitter specifically designed to deliver RF energy for harvesting by the antenna. The transmitter can be configured as a standalone device or integrated into an existing device.

Conversion of the Energy into DC

[0152] The RF energy captured by the antenna must be converted into a useful form of energy for the specific device. This conversion is shown in block form in all FIGS. **1-90**) as the RF power harvesting **20** block. The most common form of useable energy is DC energy. To perform this conversion, the block includes circuitry to rectify the captured alternating current (AC) energy to create DC energy. The rectification in this block can be done with a diode(s), a transistor(s), or some other rectifying device or combination.

Regulation of the Energy

[0153] It may be necessary to regulate the converted power (hold the power at a constant level) for specific devices. FIGS. **2-7**, **10-17**, and **22-53** show how this regulation can be implemented using a power regulation **26** and/or power storage circuit **28** block. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications. The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or a switching regulator **26** to hold the voltage at a constant level. Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

Storage of the Energy

[0154] If a device has intermittent power requirements, such as the devices exampled by FIGS. **2-53**, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block or the power regulation **26** and/or power storage circuit **28** block. Storage devices can include, but are not limited to, a battery, a capacitor, or another type of power storage component. In certain applications, it may be necessary to include additional circuitry that controls how the power is transferred to the storage device. The power storage charger **30** block is shown in FIGS. **18-53**. This may be needed if the power storage component requires a special charging mechanism such as pulse charging or trickle charging. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. There are devices that will not require storage. These devices can run directly off of the converted power. These devices also may or may not require regulation of the captured power.

Supplying the Power

[0155] The captured DC power, which may or may not be regulated and/or stored, is supplied to the device, which is represented by the core device **22** components block in the figures. This may be a single connection or it may supply multiple parts of the device with power.

[0156] RF energy harvesting also has the ability to be augmented by other types of power harvesting or storage components. Other power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. FIGS. **60-88** show how the alternative power sources **24** block can be connected to an RF energy harvesting system. These figure show how the RF energy harvesting **20** block and the alternative power sources **24** block can work independently or have communication with each other. The antenna configurations shown in FIGS. **54-59** are still applicable with the addition of an alternative power sources **24** block. These antenna configurations can be applied to FIGS. **60-88**.

[0157] RF energy harvesting also has the ability to provide a backup to devices on-grid (tethered) or with reliable power sources, which can be used in case the primary power source is lost. As an example, it may be mandated by regulations that a sensor has auxiliary power in case the primary supply is lost. It could be possible to use a rechargeable battery that obtains its charge from the primary supply when in operation. However, if the primary supply is lost for a time greater than the life of the rechargeable battery, the specification of uninterrupted power is not met. RF energy could be used to supply power to the described device while the primary supply is not available. The primary supply could include, but is not limited to, an on-grid connection, a generator, a battery, or other reliable power supply.

[0158] RF energy harvesting with or without alternative source augmentation is applicable to provide electric power directly or indirectly to a range of electronic components contained in any specific electrical or electronic device and includes, but is not limited to:

[0159] Passive electronic components, active electronic components;

[0160] Resistors, fixed resistors, variable resistors, thermistors, thyristor, thermocouple;

[0161] Capacitors, Electrolytic Capacitors, Tantalum Capacitors, Ceramic Capacitors, Multilayer Ceramic Capacitors, Polystyrene Film Capacitors, Electric Double Layer Capacitors (Super Capacitors), Polyester Film Capacitors, Polypropylene Capacitors, Mica Capacitors, Metallized Polyester Film Capacitors, Variable Capacitors ;

[0162] Diodes, Voltage regulation diodes, light-emitting diodes, organic light-emitting diodes, Variable capacitance diodes, Rectification diodes, Switching diodes, Regulation Diodes, Diode bridges, Schottky barrier diodes, tunnel diodes, PIN diodes, Zener diodes, Avalanche diodes, TVSs;

[0163] Integrated circuits, microcontroller unit (MCU), microprocessor unit (MPU), logic circuits, memory, printed circuits, circuit boards, printed wiring boards;

[0164] Transistors, MOSFETs, FETs, BJTs, JFETs, IGBTs, Relays, Antennas, semiconductors, conductors, inductors, relays, diacs, triacs, SCRs, MOVs;

[0165] Fuses, circuit breakers;

[0166] Batteries, Non-rechargeable batteries, rechargeable batteries, coin cell batteries, button cell batteries, alkaline batteries, lithium batteries, lithium ion batteries, lithium polymer batteries, NIMH batteries, NICAD batteries, Lead acid batteries, Zinc air batteries, Manganese Lithium batteries, Niobium Titanium Lithium batteries, Vanadium Pentoxide Lithium batteries, Carbon

Zinc batteries, Zinc Chloride batteries, Lithium Thionyl Chloride batteries, Manganese Dioxide batteries, Lithium Poly-Carbonmonofluoride batteries, Lithium Manganese Dioxide batteries, Lithium Chloride batteries, Lead Acid Calcium batteries, Lead Acid Tin batteries, Oxy Nickel batteries, Silver Oxide batteries, Magnesium batteries;

[0167] Inductors, Coils, High Frequency Coils, Toroidal Coils, Transformers, switches, chokes;

[0168] Motors, DC motors, stepper motor, AC motors, Fans;

[0169] Crystals, Oscillators, Clocks, Timers; and

[0170] Displays, LCDs, LED displays.

[0171] RF energy harvesting with or without alternative source augmentation is applicable across a range of markets and specific devices and includes but is not limited to:

[0172] Consumer electronics:

[0173] Electronic equipment, wired devices, battery powered devices, wireless communication devices, cell phones, telephones, phones, cordless phones, portable phones, Bluetooth devices, Bluetooth headsets, hands-free headsets, headsets, headphones, Wireless headsets, radios, AM/FM radios, shortwave radios, weather radios, Two-way radios, portable radio, lights, lanterns, portable lights, flashlights, nightlights, spotlights, search lights, calculators, graphing calculators, desk calculators, clocks, alarm clocks, wall clocks, desk clocks, travel clocks, watches, wristwatches, pocket watches, stop watches, timers, voice recorders, Dictaphones, laser pointers, power tools, cordless power tools, electronic razors, electric razors, handheld games, gaming systems, game controllers, wireless game controllers, remote controls, battery chargers, computers, portable computers, keyless entry, toys, toy guns, toy laser guns, games, microphones, musical instruments, musical effects processors, musical instrument tuners, metronomes, electronic chord charts, door openers, garage door openers, PDA, Cameras, Video recorders, Multimeter, electronic test equipment, hand-held electronics, portable electronics, wireless pens, sound generators, noise generators, language translators, electric toothbrushes, portable televisions, pagers, transceivers, toy vehicles, remote control vehicles, toy planes, remote control planes, pet containment systems, invisible fence pet sensors, memory backup, base station battery backups, appliance battery backups, uninterrupted power supplies, GPS devices, memory retention power supplies, metal detectors, stud finders, metal stud finders, stun guns, tazers, wearable devices, baby monitors, intercoms, doorbells, wireless doorbells, electronic office supplies, electronic staplers, radar jammers, radar detectors, digital scales, microfilm cassettes, video head testers, compasses, noise canceling headphones, air samplers, depth finders, barometers, weather measurement instruments, data transfer devices, automatic distress signaling unit, Wireless audio speakers, Satellite radios, Police scanners, Car navigation systems (GPS devices), Decorative lights, Christmas lights, garden lights, lawn lights, ornamental lights, porch lights;

[0174] Multi-media players: MP3, DVD, analog music players, CD players, tape players, digital music players, digital video players, minidisc; and

[0175] Computer: keyboards, mice, peripherals, computer equipment, electronic computers, computer storage, computer terminals;

[0176] Building/Industrial Automation:

[0177] Sensors: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity, glass breakage, break beam detector;

[0178] Controls: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity; and

[0179] Devices: Thermostats, light switches, door locks, smart-card door locks, lighting, emergency lighting, motion lighting, safety lighting, highway lighting, construction lighting, sign lighting, roadway sign lighting, construction sign lighting, automatic flushing units, automatic soap dispenser, automatic paper towel dispenser, automatic faucets, automatic door sensors, identification reader, fingerprint reader, credit card readers, card readers, valve actuators, gauges, analog gauges, digital gauges, fire extinguishers, wireless switches, remotely operated inspection equipment, gas/oil pipeline monitoring systems, robotic pipeline inspection gauges, “auto-reclosers” for electric power lines, sonar buoys, telemetry systems, electronic record tracking systems, robbery tracking devices, interrogators, programmers, emergency exit alarms, alarms, flood alarms, gas alarms, electronic entry systems, security keypads, silo transducers, data recorders, signal tracers, anti-static strap testers, radiosonde weather balloons, utilities load controllers, profilometers, noise cancellation equipment, infrared beacons;

[0180] Military/Government:

[0181] Tracking tags: Weapons, vehicle, soldier, gear/assets, staff, general population, security access badges;

[0182] Sensors: Proximity, intrusion, environmental, chemical/biological; and

[0183] Equipment: Battery charger, surveillance, card readers, identification reader, fingerprint reader, retinal scanners, satellites, rockets, space vehicles, search and rescue transponders (SARTs), emergency position-indicating rescue beacons (EPIRBs), emergency locator transmitters (ELTs), military radios, electronic toll collection systems, postal tracking systems, communica-

tions, thermal imaging, night vision, training targets, field medical equipment, house arrest monitors, laser tags, electronic parking meters, multiple integrated laser engagement system, munitions and mines, ship sensors;

[0184] Utility:

[0185] Gas consumption meters, water consumption meters, and electric consumption meters;

[0186] Logistics & Supply Chain Management:

[0187] Radio-frequency identification devices (RFID), RFID readers;

[0188] Tracking: Asset tags, cargo container location beacons, transponders, transceivers; and

[0189] Devices: Smart price tags, smart shelving, hand-held barcode scanner, barcode scanners, credit card readers, card readers, retail signage, hotel door locks;

[0190] Homeland Security:

[0191] Sensors: Occupancy, proximity, environmental, chemical/biological, motion, position; and

[0192] Metal detector wand;

[0193] Medical:

[0194] Implantable: cochlear implants, neural stimulators, pace makers, medication administration, defibrillator;

[0195] Body function monitors: pressure, temperature, respiration, blood oxygenation, insulin, hearing aid, pulse, EKG, heart, Holter;

[0196] Tracking tags: Patient, baby identification, assets, supplies, staff, medication, instruments;

[0197] Devices: Home healthcare equipment, ambulatory infusion pumps, blood analyzers, biofeedback systems, bone growth stimulators, thermometers, digital thermometers, stimulators, galvanic stimulators, muscle stimulators, pediatric scales; and

[0198] Agriculture—livestock tracking and asset tracking:

[0199] Tracking: livestock, asset, wildlife tracking devices; and

[0200] Equipment: cattle prods;

[0201] Automotive:

[0202] Automotive antennas, Automotive Audio Systems, Automotive Lighting, Automotive Video Systems, Computers, Processors, Controls, Switches, Electric Motors, Actuators, Ignition Systems, Starter Systems, Injection Systems, Powertrain Electronics, Radar Detectors, Proximity Detectors, Safety Systems, Security Systems, Sensors, Regulators, Distributors, Vehicle Control, Wiper Systems, Washer Systems, Radio, Video Systems, Entertainment Systems, Navigation Systems, GPS systems, Power Mirror Systems, Emission control systems;

[0203] Appliances:

[0204] Monitoring systems and control systems for major and small appliances including washing machines, dryers, refrigerators, freezers, coolers, air conditioners, humidifiers, dehumidifiers, air purifiers, air filters, fans, furnaces, water heaters, boilers, space heaters, sowing machines, ice makers, microwave ovens, convection ovens, ovens, toaster ovens, ranges, range hoods, cooktops, stoves, stovetops, crock pots, hot plates, dishwashers, garbage disposals, can openers, vacuum cleaners, blenders, mixers, food processors, irons, coffee makers, toasters, grills, hair dryers, electric tooth brushes, electric razors, electric drills, electric screwdrivers, chainsaws, lawnmowers, push mowers, riding mowers, trimmers, brush cutters, pruners, edgers, vending machines;

[0205] Ventilation, Heating, Air-Conditioning, and Commercial Refrigeration Equipment:

[0206] Monitoring systems, control systems;

[0207] Engine, Turbine, and Power Transmission Equipment;

[0208] Monitoring systems, control systems;

[0209] Other General Purpose Machinery Manufacturing:

[0210] Monitoring systems, control systems;

[0211] Telecommunications:

[0212] Monitoring systems, control systems;

[0213] Portable;

[0214] Aircraft:

[0215] Monitoring systems, control systems, actuator systems, sensors.

[0216] It should be noted that devices within a specific category may be applicable across multiple areas even if they are not specifically listed. (e.g., temperature sensors apply to Industrial and Building Automation and Appliances).

[0217] To retrofit or redesign the devices listed, it is possible to implement the described systems in numerous ways. It may be advantageous to leave the device design as-is including the existing power supply. As an example, a device may use non-rechargeable batteries to operate. The device will most likely have a protection circuit to prevent damage if the batteries are installed incorrectly. The protection mechanism is commonly a diode inline with the positive terminal of the battery. In this case, the RF power harvester **20** with or without the alternative power source **24** could be inserted, with an antenna, into the device. The power generated by the RF power harvester **20** (and the alternative power source **24**, if applicable) could be connected to the device after the protection mechanism described to avoid potential charging of a non-rechargeable battery.

[0218] Another way to configure the device's power system is to replace the non-rechargeable batteries with rechargeable batteries. In this instance, the output from the RF power harvester **20** (and alternative power source **24**) could be connected to either side of the protections device. If the connection is before the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will recharge the battery and supply power to the device. If the connection is after the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will supply power to the device and the battery will supply any extra power needed that could not be supplied by the RF power harvester **20** (and the alternative power source **24**, if applicable). It should be noted that the protection device in this case is not needed for proper operation. Its only function would be to protect the batteries from being installed incorrectly. An antenna could be contained inside or placed on the outside of the device.

[0219] Another configuration of the device's power system is to remove the existing batteries and install the RF power harvester **20** (and the alternative power source **24**) in the enclosure provided for the batteries. An antenna could be contained inside or placed on the outside of the device.

[0220] Yet another method of configuring the device's power system would be to reduce the number of batteries and replace them with the RF power harvester **20** (and the alternative power source **24**). In this case, the output from the system would be connected to the batteries in series or par-

allel depending on the original battery configuration. An antenna could be contained inside or placed on the outside of the device.

[0221] An additional option, would be to completely redesign the product and integrate the required circuitry and storage components into the device. This method is probably the most advantageous because it can fully take advantage of the benefits offered by the RF power harvester **20** (and the alternative power source **24**). An antenna could be contained inside or placed on the outside of the device.

[0222] If the RF power harvester **20** (and the alternative power source **24**) is used as a backup to the primary power supply, a switch could be implemented into the system in order to switch the RF power harvester **20** (and the alternative power source **24**) on when the primary source is lost. In this case, an antenna could be contained inside or placed on the outside of the device.

[0223] To show the flexibility of RF energy harvesting, several products were retrofitted to include an RF power harvester **20** (energy harvesting circuitry). These products include a wireless keyboard, a wall clock, and a desk calculator.

[0224] The wireless keyboard is an example of recharging and augmenting a battery to supply power to a device. This system is shown in FIG. **13**. The output from the regulation circuitry recharges the battery and supplies power to the keyboard. The battery is also used to supply power to the keyboard. The keyboard also includes a separate antenna for receiving power and for data communications. The antenna configuration can be seen in FIG. **55**.

[0225] The wall clock is an example of a direct powering system. The wall clock was retrofitted to include an RF power harvester **20** and the internal AA battery was removed. This system is shown in FIG. **2**. The wall clock did not need regulation, but did require a capacitor for storage to supply the pulse of power to move the second hand.

[0226] The calculator is an example of using RF energy harvesting with another energy harvesting technology. The calculator had an internal 1.5V coin cell battery and a small solar panel. The internal battery was removed, however, the solar panel was left intact. This system is shown in FIG. **60**. In this system, the calculator can receive power from both the solar panel and the RF power harvester **20** to eliminate the need for a battery.

[0227] As an additional example, an RF power harvester **20** (energy harvesting circuit) similar to the ones shown in U.S. Pat. No. 6,615,074 (FIGS. 8, 9, 12*a*, 12*b*, 13, 14), was connected in series with a 0.5V solar cell. Individually, the solar cell was able to provide 0.480V to a 10 kilo-ohm resistor, which was being used to simulate the core device **22** components. This corresponds to 23 microwatts. The RF power harvesting circuit by itself was able to provide 2.093V across the 10 kilo-ohm resistor when being supplied by 1 milliwatt of RF power. This corresponds to 438 microwatts. The two circuit outputs were then combined in series by connecting the output from the RF energy harvesting circuit to the ground of the solar cell. The output of the solar cell was then connected to the resistor. The other end of the resistor was connected to the ground of the RF energy harvesting circuit. The voltage across the resistor with the circuits connected as shown in FIG. **63** was 2.445V. This corresponds to 598 microwatts.

[0228] As can be seen, the combination of the two technologies produces a result higher than the addition of the individual powers. From this, it can be determined that the two technologies can cooperate in a way that produces favorable results.

[0229] In the example given, the solar cell produces current to supply the load and helps to bias the RF rectifying diodes, which allows the RF energy harvesting circuit to operate a higher efficiency. The solar cell also changes the impedance seen by the RF energy harvesting circuit, which produces a beneficial result. To be more specific, when examining the power output of the individual circuit (solar and RF power harvesting), the sum of the power captured by the individual circuits was 23 μW+438 μW=461 μW. However, when the two circuits are combined and are allowed to work in conjunction with one another, the output power becomes 598 μW. This result shows that combining the two power-harvesting technologies produces a 30 percent increase in the output power for this example. This same technique can be applied to multiple energy harvesting technologies to produce even greater output power. The equations for this example are shown below.

[0230] Individual Circuits

$$P_1=P_1+P_2+\ldots+P_N$$

[0231] Combined Circuits

$$P_C>P_1=P_1+P_2+\ldots+P_N$$

[0232] where P_1 is the sum of the individual output powers

[0233] P_C is the output of the combined circuit

[0234] P_1 is the output power from the first power harvesting technology

[0235] P_2 is the output power from the second power harvesting technology

[0236] P_N is the output power from the N^{th} power harvesting technology

[0237] N is the number of power harvesting technologies or circuits.

[0238] As can be seen by the previous examples, RF energy harvesting can be used alone or in conjunction with alternative power sources to power a wide range of devices. The addition of RF energy harvesting technology to the device allows for increased battery life, increased functionality, or the removal of the primary battery.

[0239] Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

What is claimed is:

1. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source that is remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage to produce a first power associated with the DC voltage;

a regulator coupled to the power harvester and configured to regulate the first power associated with the DC voltage to produce a regulated power;

an alternative power source configured to produce a second power different from the first power and the regulated power; and

a radio-frequency identification (RFID) device electrically coupled to the antenna and configured to wirelessly communicate with the source via the antenna, the RFID device electrically coupled to the alternative power source, the power harvester and the regulator, the RFID device including an integrated circuit configured to operate based on at least one of the first power received from the power harvester, the regulated power received from the regulator, or the second power received from the alternative power source.

2. The apparatus of claim **1**, wherein the alternative power source is a rechargeable battery.

3. The apparatus of claim **1**, wherein the antenna is configured to wirelessly receive energy from the source, which is located in a far-field region of the antenna.

4. The apparatus of claim **1**, wherein the alternative power source is electrically coupled to the power harvester and is configured to supply at least a portion of the second power to the power harvester to operate the power harvester.

5. The apparatus of claim **1**, wherein the alternative power source is configured to supply the second power to the RFID device when at least one of the first power or regulated power being supplied to the RFID device is below a threshold level.

6. The apparatus of claim **1**, wherein the alternative power source is a non-rechargeable battery, the apparatus further comprising:

a protection mechanism electrically coupled to the non-rechargeable battery and configured to prevent charging of the non-rechargeable battery when the RFID device is receiving at least one of the first power from the power harvester or the regulated power from the regulator.

7. The apparatus of claim **6**, wherein the protection mechanism is a diode electrically connected to a positive terminal of the non-rechargeable battery.

8. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source that is remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage to produce a first power associated with the DC voltage;

an alternative power source electrically coupled to the power harvester and configured to produce a second power different from the first power, the alternative power source configured to supply the second power to the power harvester such that the power harvester operates, at least in part, based on the second power; and

an integrated circuit electrically coupled to the power harvester and configured to operate based, at least in part, on the first power received from the power harvester.

9. The apparatus of claim **8**, further comprising:

a regulator electrically coupled to the power harvester and the integrated circuit, and configured to regulate the first power from the power harvester to produce a regulated power, the integrated circuit configured to operate based on the regulated power received from the regulator.

10. The apparatus of claim **8**, wherein the alternative power source is electrically coupled to the integrated circuit such that at least a portion of the second power produced by the alternative power source is supplied to the integrated circuit to operate the integrated circuit.

11. The apparatus of claim **10**, wherein the alternative power source supplies a first portion of the second power to the power harvester, and a second portion of the second power to the integrated circuit when the first power received from the power harvester at the integrated circuit is below a threshold level.

12. The apparatus of claim **8**, wherein the alternative power source is a non-rechargeable battery, the apparatus further comprising:

a protection mechanism electrically coupled to the non-rechargeable battery and configured to prevent charging of the non-rechargeable battery when the integrated circuit is receiving the first power from the power harvester.

13. The apparatus of claim **12**, wherein the protection mechanism is a diode electrically connected to a positive terminal of the non-rechargeable battery.

14. The apparatus of claim **8**, wherein the alternative power source is a rechargeable battery.

15. The apparatus of claim **8**, wherein the antenna is configured to wirelessly receive energy from the source, which is located in a far-field region of the antenna.

16. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source that is remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage to produce a first power associated with the DC voltage;

an alternative power source electrically coupled to the power harvester and configured to receive the first power from the power harvester, the alternative power source configured to produce a second power that includes the first power; and

an integrated circuit electrically coupled to the alternative power source and configured to operate based on the second power received from the alternative power source.

17. The apparatus of claim **16**, wherein the alternative power source is a solar cell connected in series with the power harvester.

18. The apparatus of claim **16**, wherein the alternative power source is a solar cell configured to bias the power harvester.

19. The apparatus of claim **16**, wherein the alternative power source is configured to produce a third power independent of the first power,

the second power produced by the alternative power source being greater than the sum of the first power and the third power.

20. The apparatus of claim **16**, wherein the antenna is configured to wirelessly receive energy from the source, which is located in a far-field region of the antenna.

(57) **ABSTRACT**

A rectifier comprising a chain of transistors for RF-DC conversion. In order to compensate for the thresholds of the transistors, each transistor can be connected to a junction earlier or later in the chain. By using both p-type and n-type transistors in the same chain, the different types of transistors can be compensated in different directions allowing more transistors to be compensated. Additional transistors connected to the gates of transistors of the main chain can allow the transistors of the main chain to be forward compensated at one part of the input cycle and backward compensated in another part to minimize both the voltage threshold of the rectifier and the leakage current. The line for compensation of the voltage threshold during forward conduction can comprise a solid line or a transistor, and if a transistor is used it may be diode-connected.

RF-DC POWER CONVERTER

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit under 35 USC 119(e) of U.S. provisional application Ser. No. 62/011,957 filed Jun. 13, 2014.

TECHNICAL FIELD

[0002] Rectification, particularly for RF energy harvesting.

BACKGROUND

[0003] The vision of realizing Internet of Things (IoT) pervasively connecting large number of sensors and devices requires development of novel solutions that scavenges ambient energy to supply the power required for the operation of the sensors. Relying on batteries as the source of energy for wireless sensors impose several limitations including the need for routine maintenance/charging of batteries, operation interruption and cost involved in replacing batteries specially those employed in harsh environments, and challenges of scaling of battery-powered wireless sensors to millions of nodes. RF energy from ambient sources can be used to power efficiently the sensor networks with or without batteries. In addition, they can also be used to partially/fully charge other portable electronic devices to extend their battery life.

[0004] There is accordingly a growing interest in harvesting ambient energy to partially/fully supply the energy required for the operation of portable electronic devices. Scavenging energy from the ambient electromagnetic wave referred as RF energy harvesting is one of the most popular method for powering low-power wireless sensors. As most of today's integrated circuits are fabricated in CMOS technology, it is highly desirable to integrate RF energy harvesting systems with the rest of the system on a single CMOS chip for reduced cost and small form factor. RF powered devices are widely used in wireless sensor networks operating at power levels of 10 to 100's of μW. RF energy harvesting can be used in applications where the traditional energy sources such as light, vibrations are not available.

[0005] In an RF energy harvesting system **20** as shown in FIG. **1**, an antenna **22** receives the incident RF signal, an impedance matching circuit **24** maximizes the power transfer from the antenna to the power converter **26**, and a RF-DC power conversion circuit **26** converts the incident RF power to DC output power. The output DC voltage is stored in an energy storage component **28** (battery or capacitor) or can directly power the wireless sensors. The major challenge of scavenging RF energy is the limited signal strength of the RF waves and the low efficiency of the harvesting circuit at low input power.

[0006] The radiated signals are received by the RF energy harvesting system **20** and converted into a DC output voltage which is used to power-up the system. The radiated signals have to adhere to the regulation standards set by the federal communication commission (FCC). The unlicensed industrial, scientific and medical (ISM) band with a center frequency of 915 MHz operating at 902-928 MHz with a maximum effective isotropic radiated power (EIRP) of 4 W can be used for RF energy harvesting. The major challenge of scavenging RF energy is the limited signal strength of the RF waves and the low efficiency of the harvesting circuit. The signal strength is limited due to the attenuation in the signal due to the free space loss. Also, the power at the transmitter level cannot be increased without violating the FCC guidelines. Hence modification has to be done at the receiver side. The power consumption for the commercial sensor network nodes vary based on the manufacturers and has been estimated by various authors to be around 10 to 100 μW depending on the sensing application and the radio protocol. A multivolt supply voltage is typically required for the operation of the sensor circuitry.

[0007] The power harvester unit **20** comprising a multistage rectifier **26** is a key component in RF energy harvesting systems. It converts the incoming weak RF signal into a DC voltage. The performance of the rectifier unit **26** can be evaluated based on its power conversion efficiency (PCE) which is the ratio of power delivered to the load to the input power, based on sensitivity i.e. the minimum input power required for production of a DC voltage at the output and finally based on output DC voltage levels. To increase rectifier's PCE, the energy losses such as those introduced by the non-zero ON resistances of the rectifying devices must be reduced. To increase sensitivity and output voltage levels, rectifying devices with lower threshold voltages are required. Hence, these performance parameters of the power harvester are strongly affected by the threshold voltage of the rectifying devices. The power level has to exceed the threshold voltage of the rectifying device to turn on the rectifier unit in the RF-DC power conversion circuit. The minimum power is referred as the power-up threshold of the system. In terms of voltage level, a minimum input voltage is required for the circuit operation and is referred as the dead-zone of the rectifier.

[0008] The performance of an RF energy harvesting system **20** is significantly affected by the threshold voltage of the rectifying device **26**, the voltage that is required to turn on the semiconductor devices used as rectifying devices. A rectifying device **26** with lower threshold voltage enables the operation of RF-DC power converter **26** at low input power levels significantly reducing the power-up threshold of the rectifiers, and increasing the output voltage level for the same input power. The threshold voltage of device can be reduced using different technology-based approaches for the devices including silicon-on-sapphire (SOS), schottky diodes such as silicon-titanium schottky diodes or SMS and the HSMS diodes, special low-threshold-voltage transistors in CMOS process, and floating gate transistors which store a precharged voltage at the gate to lower the threshold voltage. The drawback of using technology-based approaches is additional fabrication steps that increases the production cost and prevents integration of RF energy harvester in mainstream Complementary Metal-Oxide-Silicon Integrated Circuits (CMOS ICs). Active/passive circuit techniques can be alternatively used to reduce the threshold voltage of the device. Active technique requires an external power source or secondary battery and is generally used in active sensors or active RFID. This enables more sophisticated applications at the price of increased cost and maintenance. Passive techniques do not require an additional source of energy but may require additional circuit where an auxiliary rectification chain is used to generate the compensating threshold voltage for the main RF-DC power conversion circuit. The auxiliary chain requires additional power and occupies additional area. An internal threshold voltage cancellation circuit was introduced in Kocer et al. where the compensating voltage was generated passively and stored in a capacitor that is applied at the gate-source terminal of the MOS transistor. This technique requires a large resistance and high capacitance value which leads to a large area on the chip. A self-biasing technique consisting of an off-chip high impedance resistive network was used by Li et al. to provide DC biasing voltages. Another technique can be using floating gate transistors storing a pre-charged voltage at the gate lowering its threshold voltage. The threshold voltage can be varied by changing the body-source potential of the transistor. This technique requires an additional pre-charge phase making it unsuitable for fully battery-less applications. The RF-DC power conversion circuit consisting of NMOS transistors with grounded body terminal leads to an increase in the threshold with the number of stages due to the body effect. This degrades the efficiency of the power conversion circuit. The body terminal of the transistors can be dynamically controlled using additional circuit or floating well devices. The floating well technique generates undesirable substrate current. Also, a triple-well source-body connected device has high parasitic capacitance leading to reduced efficiency. A cross-coupled differential scheme was used in Sciorcioni et al. consisting of triple-well NMOS and standard PMOS transistors to reduce the threshold voltage. A self-compensation scheme based on the Dickson topology was introduced in Curty et al. consisting of triple-well NMOS transistors to provide individual body biasing. The compensating voltage was provided by connecting the gate terminal to later stages. The design of the power converter in the works was focused on only reducing the threshold voltage neglecting the key role played by the reverse leakage current in introducing power losses. The reduction in threshold voltage increases the reverse conduction current causing additional loss.

[0009] To address the trade-off between the reduced threshold voltage and increased leakage current, Lee et al. proposed use of high speed comparators to control the reverse leakage current. The use of comparator increases the power consumption and limits the usefulness of this technique to low-frequency applications. Dynamic CMOS Dickson pump has been designed in previous works to eliminate the V_{th} drop while reducing the reverse leakage current. These circuits are designed for digital application with no emphasis on low-power operation. Differential-drive (**4**T-cell) architecture with the cross coupled bridge configuration and its variant has been used in previous works to reduce the threshold voltage as well as lower the leakage current. Differential circuit requires a PCB balun for the single-ended to differential conversion or differential antenna. Also, the differential circuit requires triple-well NMOS transistors and larger number of rectifying devices for the same number of stages compared with single-ended one.

SUMMARY

[0010] A power conversion circuit is provided having a first input line and a second input line, the first and second input lines configured to receive an alternating voltage differential between the first and second input lines, a multi-stage rectifier comprising transistors arranged in series, each transistor having a gate, a source and a drain, adjacent transistors of the series being connected so that for adjacent p-type transistors the drain of the left p-type transistor is connected to the right adjacent source of the right p-type transistor and source of the right p-type transistor is connected to the left adjacent drain of the left p-type transistor, for adjacent n-type transistors the source of the left n-type transistor is connected to the right adjacent drain of the right n-type transistor and drain of the right n-type transistor is connected to the left adjacent source of the left n-type transistor, for a p-type transistor adjacent to an n-type transistor the source of the right p-type transistor is connected to the source of the left adjacent n-type transistor and drain of the left p-type transistor is connected to the drain of the right adjacent n-type transistor to form a junction, each junction being connected to one of the first input line and the second input line via a capacitor, with adjacent junctions having one junction of the adjacent junctions connected to the first input line and the other junction of the adjacent junctions connected to the second input line, the gate of each transistor of the multi-stage rectifier being connected to a respective junction that is not a junction formed by the connection of that transistor to an adjacent transistor but a junction in the previous stage for the p-type transistor or later stage for the n-type transistor, at least one of the transistor in the multi-stage rectifier being p-type and at least one being n-type.

[0011] In various embodiments, there may be included any one or more of the following features: There may also be an auxiliary chain of p-type transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to a p-type transistor of the multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the previous stage junction of the main chain which is N transistors away from the respective transistor, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of the later stage transistor in the main chain. There may also be a diode connected transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of previous stages which is N transistors away from the respective transistor. There may also be an auxiliary chain of n-type transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to an n-type transistor of the multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the later stage junction of the main chain which is N transistors away from the respective transistor, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of the previous stage transistor in the main chain. There may also be a diode connected transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages which is N transistors away from the respective transistor.

[0012] There is also provided an auxiliary chain of transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to a respective transistor of a main chain of a multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the later stage junction of the main chain which is N transistors away from the respective transistor in the case that the respective transistor is n-type, or to the earlier stage junction of the main chain which is N transistors away from the respective transistor in the case that the respective transistor is p-type, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of a previous stage transistor in the main chain, in the case that the respective transistor is n-type, or to the junction of a later stage transistor in the main chain, in the case that the respective transistor is p-type.

[0013] In various embodiments, there may be included any one or more of the following features: the transistors of the main chain and auxiliary chain may be n-type and there may also be a p-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages, such that the gate of the additional p-type auxiliary transistor is connected to the gate of the n-type auxiliary transistor and the source of the n-type and p-type auxiliary transistors are connected, and the drain of the p-type auxiliary transistors is connected to junction of the main chain which is at 'N' later stages from the respective transistor. The transistors of the main chain and auxiliary chain may be p-type and there may also be an n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of earlier stages, such that the gate of the additional n-type auxiliary transistor is connected to the gate of the p-type auxiliary transistor and the source of the n-type and p-type auxiliary transistors are connected, and the drain of the n-type auxiliary transistors is connected to junction of the main chain which is at 'N' earlier stages from the respective transistor. There may also be a diode connected p-type or n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages which is N transistors away from the respective transistor. There may also be a diode connected p-type or n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of earlier stages which is N transistors away from the respective transistor.

[0014] In any of the above embodiments, there may be included any one or more of the following features: There may also be an additional transistor connected in series with the multistage rectifier, the additional transistor having a gate, a source and a drain, the gate of the additional transistor being connected to the drain of the additional transistor. The gate of each transistor in the main chain may be connected to the junction of previous stages for p-type transistor and later stages for n-type transistor. N of the transistors in the multistage rectifier arranged in series may be n-type and all but N of the transistors in multistage rectifier arranged in series may be p-type. The second input line may be grounded. The body terminal of each p-type transistor may be connected to the respective drain and the body terminal of each n-type transistor may be either grounded or connected to the respective drain terminal.

[0015] These and other aspects of the device and method are set out in the claims, which are incorporated here by reference.

BRIEF DESCRIPTION OF THE FIGURES

DETAILED DESCRIPTION

[0047] There is provided a hybrid forward and backward threshold voltage compensation scheme for RF-to-DC power conversion. In an embodiment, PMOS transistors are used as rectifying devices in all stages except for the first few stages eliminating the need for triple-well NMOS transistors. The compensating voltage is provided by connecting the gate terminal of the PMOS transistors to previous stages, also referred to as back-compensation, and also by connecting the gate terminal of the initial few NMOS transistors to later stages. Using PMOS transistors as a rectifying device in all the stages except for the first few stages eliminate the need for triple-well NMOS transistors. Also, all the MOS transistors in the main rectification chain are compensated in the proposed scheme. In addition to the hybrid scheme, an adaptive method suitable for rectifying devices operating at low power level is proposed to control the ON/OFF operation of the MOS transistors in the main rectification chain. An auxiliary block consisting of PMOS transistor is introduced to control the switching of the MOS transistors in the main chain. The PMOS transistors in the main chain are back-compensated in the conduction phase and forward-compensated when not conducting; increasing the gate-source potential and reducing the reverse leakage. The controlling voltage of the transistors in the auxiliary chain is derived from the local node of the main chain. Moreover, a procedure for designing matching network to provide passive voltage amplification and maximum power transfer is proposed. The dead-zone of the power converter unit is obtained using Y parameter analysis and the matching circuit is designed at the point of maximum power transfer. The RF-to-DC power conversion circuit may be fabricated using conventional methods such as IBM's 0.13 μm CMOS technology.

[0048] Power Harvester Circuit

[0049] FIG. **1** shows a block diagram of the power harvester unit of an RF energy harvesting system **20**. In the RF energy harvesting system shown, the signal is received by an antenna **22**. An impedance matching circuit **24** comprising a high quality factor (Q) resonator is used to ensure that maximum power is transferred from the receiver to the rectifier block **26**. However, the matching network itself introduces some energy losses because of the limited quality factors of on-chip passive inductors and capacitors required to match the input impedance of the rectifier to the output impedance of the antenna. The high Q resonator can also provide passive voltage amplification of the input signal. Depending on the embodiment, the high Q resonator may have a fixed frequency or may be tuneable. The next block is the RF-to-DC power conversion circuit **26** that converts the RF signal to DC voltage. The rectifier preferably operates at low input power levels while providing high power conversion efficiency. Several rectifier units may be cascaded to increase the overall output voltage, referred collectively as a voltage multiplier. There may be a power management block (not shown) to control the flow of power from the energy harvester to the load. The harvested power is then finally used to charge an energy storage device **28** such as a battery or a capacitor, which in turn powers a load **30**. Alternatively, the energy storage device may be omitted and the load powered directly by the power harvester. The power management block may also be omitted with or without the energy storage.

[0050] Rectifier Circuit

[0051] In half-wave rectifiers, the rectifying device is conducting for half of the cycle, passing the input voltage to the output. However, the output voltage is lower than the input by the amount of voltage drop needed for turning ON the rectifying device. A half-wave rectifier can be implemented using diodes as shown in FIG. **2**A. The voltage drop across the device depends on the threshold voltage of the diode. FIGS. **2**B and **2**C show half-wave rectification circuits implemented using diode-connected NMOS and PMOS transistors respectively in CMOS technology. The voltage drop in this case depends on the threshold voltage of the transistor. Both diode-connected PMOS and NMOS transistors can be used as rectifying devices. FIG. **2**D shows the voltage doubler unit which is a cascade of two half-wave rectifiers. The voltage doubler rectifies the AC input in both the positive and negative cycles. Similar to the half wave rectification, the diodes are implemented by connecting the drain and the gate terminal of the MOS transistor together such that the transistor is always in saturation region in forward bias condition, as shown in FIGS. **2**E and **2**F.

[0052] The voltage doubler may be used as a basic unit in a power conversion circuit. FIG. **2**F shows an example voltage doubler. In the voltage doubler, each of the transistors conducts only during one half of the input cycle. M_{P1} conducts during the negative phase while M_{P2} conducts during the positive phase of the input cycle. Each of the transistors goes through the sub-threshold region, inverse region and the leakage region. The maximum voltage at the output of voltage doubler is $2\,\mathrm{Vamp}-|\mathrm{VTP1}|-|\mathrm{VTP2}|$, where V_{amp} is the maximum amplitude of the input signal and V_{TP1}, V_{TP2} are the threshold voltages of the diode-connected transistors M_{P1} and M_{P2} respectively. Thus the maximum possible voltage is twice the RF signal's amplitude only when the threshold voltage of the transistors is equal to zero. To understand the operation of the voltage doubler in detail, we can look at the transient analysis of the doubler circuit of FIG. **2**F, as shown in FIG. **3**A. There are three regions of operation of the circuit as seen from FIG. **3**A. It is described as follows: the sub-threshold operation extends from $V_{in}=0$ to $V_{in}=|V_{TP}|$, where V_{in} is the input voltage. The current in this region is an exponential function of the input voltage. The inversion region extends from $V_{in}=|V_{TP}|$ to $V_{in}=V_{amp}$. The current in the in this region is a square function of the input voltage. In the inversion region, the output current reaches its peak value when $V_{in}=V_{amp}$. Finally, the leakage region extends from $V_{in}=0$ to the next $V_{in}=0$ in the negative half-cycle. The current that flows through transistor M_{P2} during this time interval is referred as reverse leakage current. Thus, the actual charge transfer mechanism is only for a short duration while other parameters such as subthreshold and reverse leakage currents have to be considered for the rest of the cycle.

[0053] Several voltage doublers can be cascaded to increase the overall output voltage. These voltage multipliers are also known as "charge pumps" and can generate a voltage several times larger than their input supply voltage. The Dickson multiplier with diode-connected transistors is commonly used for integrated applications. The Dickson multiplier of

FIG. **4**A is modified for low power energy harvesting applications by grounding the ϕ_2 (out of phase) clock terminal and applying the input signal at the ϕ_1 terminal. FIG. **4**B shows the conventional Dickson multiplier with the PMOS voltage doubler as a rectifier unit. The body terminal of the transistors is connected as shown in FIG. **4**B to further reduce the threshold voltage while the transistors are conducting. For example, in the positive phase of the input cycle, transistors M_2, M_{n-1} and M_{n+1} are conducting. The source of the transistors is at a higher potential compared to the body terminal. This reduces the threshold voltage in the conducting region. At the same time, transistors M_1, M_3 and M_n are in the reverse region (leakage operation). The gate-source and the body-source potential is zero for these transistors. Thus, the threshold voltage of transistors M_2, M_{n-1} and M_{n+1} while they are conducting is lower than the threshold voltage of the transistors M_1, M_3 and M_n which are in the reverse region in the positive input phase. Similarly, in the negative phase of the input cycle, transistors M_1, M_3 and M_n which are conducting have a lower threshold voltage than the transistors M_2, M_{n-1} and M_{n+1}.

[0054] To increase the output voltage of multi-stage rectifiers, the number of rectifier stages must be increased accordingly. However, as the number of stages increases the power conversion efficiency is reduced as larger number of the transistors dissipates more power. Also, the threshold voltage of the standard MOS transistor which lies around 450 mV in 130 nm technology, reduces the sensitivity of the power harvester block. As the number of stages in the rectifier increases, the power losses increases, reducing the overall efficiency. Too few of stages, leads to low output DC voltage even if the PCE is high. To achieve a high DC voltage, large transistors have to be used, leading to high leakage and parasitic losses whereas smaller transistor size affects the charge transfer leading to low DC voltage. The strategy while designing the multi-stage rectifier circuit of FIG. **4**B is as follows: The individual stages of the voltage doubler can be cascaded to increase the output voltage. As the number of stages increases, the output voltage increases. With the increase in the number of stages, the PCE decreases and the output voltage saturates. Hence the transistors as well as the pumping capacitors are scaled while increasing the stages. The scaling is done to maintain the incremental voltage per stage and the PCE relatively constant with the increase in the number of stages. Thus the PCE can be maintained with proper device scaling while increasing the DC voltage for a constant output power. The scaling of width and the pumping capacitance with the stages results in impedance looking into the rectifier to be unchanged so that the input power and thus the PCE remains constant. Thus, when designing a multistage rectifier unit one can optimize of number of stages and width of the transistors to maximize the PCE for a given output voltage.

[0055] The standard Dickson multiplier can be modified for designs involving energy harvesters where the input voltage is low. FIG. **4**A shows an N-stage conventional Dickson multiplier. A threshold self-compensation technique was described by Dickson. The gate of the transistor in this technique is connected to the adjacent source of the transistor instead of the traditional diode-connected structure. Thus, providing bias voltage equivalent to the incremental voltage across each stage. Based on this technique, a forward compensated topology was implemented by Papotto et al. where the bias voltage was increased by extending the gate length connection. FIG. **5** shows the basic forward compensated NMOS topology.

[0056] Threshold voltage reduction techniques requiring additional circuits are not suitable for integrated low power energy harvesting applications as these circuits occupy large areas and cause additional power dissipation. Passive threshold voltage reduction technique such as the self-compensation method of FIG. **5** does not require additional circuit and can reduce the threshold voltage. In the self-compensation method, the threshold voltage of the diode-connected NMOS transistors increases with the stages due to the body effect. The body effect can be dynamically controlled using additional circuits but generates undesirable substrate current. Another alternative is using triple-well process to individually bias the body terminal of NMOS transistors and reduce the threshold voltage variation. Additional parasitic capacitance is introduced due to the well structure increasing the losses at each node and affecting the overall efficiency.

[0057] Hybrid Forward and Back-threshold compensated power converter

[0058] In order to eliminate the need for triple-well processes, we propose a threshold voltage compensation technique scheme as described below. PMOS transistors are used instead of NMOS transistors as rectifying devices. As each PMOS transistor has its own n-well, the body of PMOS transistor can be biased individually without the necessity of a triple-well CMOS process. Unlike an NMOS transistor which needs a higher potential at the gate terminal to offset the threshold voltage, a PMOS transistor requires negative gate-source potential. Therefore, the threshold voltage of PMOS transistors can be reduced by connecting the gate potential to the previous node rather than later node. As shown in FIG. **6**A, alternating input voltage V_{in} is applied on first input line **100** to odd-numbered capacitors $C_1, C_3, \ldots C_n$. Ground voltage is applied on second input line **102** to even numbered capacitors $C_2, \ldots C_{n-1}$. Capacitor C_{n+1}, while also even-numbered, is shown as connected to ground by a separate line. A third line **104** accumulates voltage for the output and is connected to ground at one end and to output at the other. In this and other figures, the end of the line having more negative voltage, which in the embodiments shown is ground, is shown at the left of line **104** and the end of the line having more positive voltage, which in the embodiments shown is the output, is shown at the right of line **104**. The capacitors are each connected to line **104**, and are numbered in the order in which they are connected to line **104** from left to right. Each capacitor maintains a respective voltage differential between the respective input line it is connected to and the part of line **104** it is connected to. This voltage differential varies over time as current flows through line **104** between capacitors. Line **104** comprises transistors $M_1, M_2, M_3, \ldots M_{n-1}, M_n, M_{n+1}$ arranged in series, a transistor being arranged between each pair of adjacent capacitors and between capacitor C_1 and ground. Adjacent transistors define junctions **106**, the capacitors being connected to the junctions. The body terminal of each transistor is connected to the drain terminal of the same transistor, as shown by dotted lines. The gate of the first transistor (for n-level compensation, the first 'n' transistors) and the last transistor are connected to their respective drains. The gates of the other transistors are connected to the drain of the transistor n+1 transistors to the left of the respective transistor. The proposed scheme as shown in FIG. **6**A reduces the threshold voltages of all PMOS transistors except the first one leading to an increased output voltage. For an n-level compensation, for the proposed scheme, there will be 'n' initial PMOS transistors that will be uncompensated as seen from FIG. **6**A To solve this problem, 'n' uncompensated PMOS transistors are replaced by NMOS transistors with grounded body terminals as seen from FIG. **6**B. As shown in FIG. **6**B, the first transistor is an NMOS transistor with a source connected to the source of the PMOS transistor to its right to define a junction and has a gate connected to the junction n stages to the right of the junction defined by its source. That is, the gate is connected to the junction defined by the source of the PMOS transistor **2** (i.e, n+1) transistors to the right. The other transistors are PMOS and, apart from the last, each has a gate connected to a junction n stages to the left of the junction defined by its source. For the purposes of the preceding statement and statements about junctions elsewhere in this document, the grounded end of line **104** can be considered to be a junction **106**A one stage from the junction defined by the connection of M_1 and M_2. Thus the compensating voltage is provided by connecting the gate terminal to later stages for the first few NMOS transistors and connecting the gate terminal to previous stages for PMOS transistors. The scheme shown in FIG. **6**A and FIG. **6**B is level-1 compensation. The compensation level can be increased by connecting the gate terminal of PMOS to the source terminals of the transistor of the following stage rather than the source of its immediate neighbor. The last transistor of the multiplier is left uncompensated to reduce the leakage. FIG. **6**C shows the proposed level-3 hybrid forward- and back-compensated multiplier. As shown in FIG. **6**C, the first **3** (i.e., n) transistors are NMOS transistors with grounded body terminals. Each NMOS (more generally, n-type) transistor has its source on the left and drain on the right, and each PMOS (more generally, p-type) transistor has its drain on the left and source on the right, where "left" and "right" are defined so that that the end of line **104** with more positive voltage is the "right", as shown in the figures. "Earlier" and "later" can also be used to mean "left" and "right". While ground is shown in the figures to the left and the output to the right, the ground could also be to the right and the output to the left. See below for a discussion of the definitions of "source" and "drain". The gates of these first **3** NMOS transistors are connected to the respective junctions **106** three (that is, 'n') stages to the right of the junctions defined by their respective sources. The remaining transistors except the last are PMOS transistors with gates connected to the junctions **106** three (that is, 'n') stages to the left of the junctions defined by their respective sources. Increasing the level of compensation leads to reduction in the threshold voltage which improves the forward conduction but also leads to increased reverse leakage current degrading the rectifier's PCE. Only odd level compensation is used as it maximizes the source-gate potential of PMOS transistors due to the alternating voltage phase with successive nodes.

[0059] To find the optimum number of stages and level of compensation, extensive simulations were conducted. FIG. **7** shows the efficiency contour plots with different level of compensation and input power level. Maximum PCE at the lowest input power level is obtained when the level of compensation is one. As the level of compensation increases, the reverse current increases which causes additional power loss and degradation in efficiency. Hence level-1 compensation gives the maximum efficiency while level-3 or higher is advantageous in reducing the threshold voltage of the RF-DC power conversion circuit. FIG. **8**A shows the constant efficiency contour plot as a function of transistor width and the number of stages for level-1 compensation. Eight-stage of doubler design equivalent to 16-stage rectifier with transistor width of 13-μm and fifteen-stage of doubler design equivalent to 30-stage rectifier with transistor width of 28 μm gives the highest efficiency contour. The former one is preferred due to lesser area on the chip. The level-1 and level-3 compensated multi-stage rectifier are referred to as efficiency circuit and voltage circuit respectively Similarly for the voltage circuit constant efficiency contour plot as a function of width and the number of stages is plotted as shown in FIG. **8**B. Twelve-stage of doubler design equivalent to 24-stage rectifier with transistor width of 8 μm is selected based on the plot. For level-3 compensation, more body-grounded NMOS transistors are required compared with the level-1. Also, the reverse leakage loss is higher for level-3 compensation due to the larger compensating voltage compared with the level-1 compensation. Increasing the level of compensation lowers the minimum input voltage requirement whereas increasing the number of stages while lowering the width of the transistors was based on the design strategy discussed earlier.

[0060] During the positive input phase, transistors M_2, M_{n-1} and M_{n+1} in FIGS. **6**A-**6**C are conducting. Since the gate terminals are connected to the previous node V_{SG} in the positive phase (conduction) is relatively high compared to the conventional Dickson multiplier. However, in the negative phase when the transistors M_2, M_{n-1} and M_{n+1} should ideally be not conducting, the V_{SG} is higher compared to the conventional case. Thus the hybrid forward and back-threshold compensated scheme is effective in increasing the forward conduction current but increases the reverse leakage current at the same time. As seen in FIG. **7**, with the increase in the level of compensation the PCE degrades. The simulated maximum PCE of 28% degrades to 11% from level-1 compensation to level-3 compensation respectively. To ameliorate this issue an adaptive scheme is proposed to control the reverse leakage current.

[0061] Especially at extremely low input power (e.g. micro-watts power level), the reverse leakage current has a significant adverse effect on the PCE and the output DC voltage of an RF rectifier as proven by the following analysis. Considering a threshold-compensated transistor of a single-stage rectifier shown in FIG. **2**G driven by an input source $V_{in}=V_a \sin \omega t$ assuming the compensation voltage is modeled by V_C and its input and the output steady-state voltage waveforms shown in FIG. **3**B, the overall PCE is defined as

$$PCE = \frac{P_{out,forward} - P_{leakage}}{P_{input}} \tag{1}$$

[0062] where $P_{out,forward}$ is the output power delivered to the load when transistor is forward-biased, $P_{leakage}$ is the output power lost due to leakage when transistor is reverse-biased, and P_{input} is the input power. The forward region extends from $t=t_1$ to $t=\pi-t_1$ with the current $I_d(t)$ through the MOS transistor M_1 as seen in FIG. **3**B.

$$\frac{P_{out,forward}}{P_{input}} = \tag{2}$$

-continued

$$\frac{\frac{1}{\pi-2t_1}\int_{t_1}^{\pi-t_1} V_{out}\cdot I_d\cdot dt}{\frac{1}{\pi-2t_1}\int_{t_1}^{\pi-t_1} V_{in}\cdot I_d\cdot dt}=\frac{\frac{1}{\pi-2t_1}\int_{t_1}^{\pi-t_1}(V_a-V_{TH}+V_c)\cdot dt}{\frac{1}{\pi-2t_1}\int_{t_1}^{\pi-t_1} V_a\sin\omega t\cdot dt}$$

Assuming the ripple voltage variation A V is much smaller than the average output voltage V_o, the output voltage for the one-stage rectifier can be expressed as $V_o=V_a-V_{TH}+V_C$ where V_{TH} is the threshold voltage of the transistor. Performing integration on (2) gives the ratio of the output power in the forward region to the input power as

$$\frac{P_{out,forward}}{P_{input}}=\frac{\omega\cdot(\pi-2t_1)\cdot(V_a-V_{TH}+V_c)}{2V_a\cos\omega t_1} \tag{3}$$

[0063] The value of t_1 lies between $0<t_1<\pi/2$ based on the value of $V_{TH}-V_C$. The time t_1 indicates the onset of inversion region and is close to zero when the compensating voltage is near the threshold voltage and will be closer to $\pi/2$ when the compensating voltage is near-zero value. As seen in (3), the ratio of the output power in the forward region to the input power increases with increased voltage compensation in the forward region. In the reverse-biased region, the leakage current is expressed as

$$I_{leak}(t)=I_o\cdot(W/L)\cdot e^{(V_{gs}-V_{TH})\eta V_T}\cdot(1-e^{-V_{ds}/\eta V_T}) \tag{4}$$

[0064] Replacing the gate-source bias voltage by V_C, source-drain bias by $V_{in}(t)-V_{out}$ and V_{in} by V_a sin wt, the leakage current as a function of time can be expressed as

$$I_{leak}(t)=I_o\cdot(W/L)\cdot e^{(V_c-V_{TH})/\eta V_T}\cdot(1-e^{(V_a\sin\omega t-V_a+V_{TH}-V_c)/\eta V_T}) \tag{5}$$

[0065] where $(\pi-t_1)<t<(2\pi+t_1)$. With increase in the compensation, the power loss increases due to the higher leakage current. As seen in (3) and (5), the ratio of the output power in the forward region to the input power even though increases with larger threshold-voltage compensation, the losses in the leakage region is higher due to the increased compensation. This indicates the fundamental trade-off between the level of threshold-voltage compensation and the leakage current of the transistors.

[0066] In a field effect transistor, the "source" and "drain" terminals are defined by the direction of flow of charge carriers when the transistor is "on": charge carriers flow from the source to the drain. For an n-type transistor, the charge carriers are electrons and for a p-type transistor the charge carriers are holes. As electrons flow from negative to positive, the source of an n-type transistor is at a lower voltage than the drain and vice versa for a p-type transistor. FETs do not necessarily have any asymmetry between the source and drain terminals beyond this. In the present system, the relative voltages of the source and drain terminals reverse in the normal course of events, as the system is exposed to alternating current in order to rectify it. There are two possible approaches to defining which terminal is the "source" and which terminal is the "drain" in this circumstance. One possible approach is to say that which terminal is the "drain" and which terminal is the "source" varies over time depending on which terminal is at the higher voltage. Thus, by this first definition, the source of an n-type transistor is whichever of the source and drain terminals has the lower voltage at any given moment, and for a p-type transistor whichever has the higher voltage at a given momentA second approach, however, is possible where the desired conduction is in a particular direction only. In the present system, conduction in one direction is desirable and conduction in the other ("leakage") is undesirable, thus the source can be defined according to which terminal is the source when current flows through the transistor in the desired direction; which terminal is considered the "source" and which terminal is considered the "drain" does not change over time in this approach despite the change in voltages. In the discussion here concerning the source-gate voltage (V_{SG}), the first approach is used, i.e. the source-gate voltage is the voltage between the gate and whichever of the source or drain terminals that has the higher or lower voltage at a given time depending on if the transistor is p-type or n-type. In addition, while the sign of a source-gate voltage difference required to operate a transistor depends on whether the transistor is p-type or n-type, V_{SG} is discussed as if the voltage to operate the transistor is always positive for p-type transistor and negative for n-type transistor. For other purposes in this document including the claims, a version of the second approach to defining which terminal is the source and which is the drain is used in which the direction of desired current is based on the desired current direction through the device as a whole. Thus, throughout the figures, p-type transistors are shown as having their sources to the left and n-type transistors are shown as having their sources to the right.

[0067] A diode-connected transistor is a transistor in which one of the source and drain terminals is connected to the gate to cause the transistor to act as a diode. A diode connected FET allows charge carriers to flow from the terminal not connected to the gate to the terminal connected to the gate, if sufficient voltage is applied, and blocks charge carriers from flowing in the opposite direction. The diode connected transistor is diode connected because it is desired that current flow in one direction is allowed and in flow in the other direction blocked. Thus, following a version of the second approach above to defining which terminal is the source and which terminal is the drain based on desired current through the individual transistor, the source or drain terminal of a diode connected transistor that is connected to the gate would be by definition the drain of the diode connected transistor. However, in this document it is the desired current through the device as a whole that is used, thus in e.g. FIG. **9**A transistor M_{na} is diode-connected and the terminal connected to the gate is depicted as the source.

[0068] To investigate the effect of the level of threshold-compensation on the PCE of multi-stage hybrid threshold-compensated rectifiers, level-1 rectifier which is connecting the gate terminal to one previous node for the PMOS transistors (FIG. **6**A) and level-3 rectifier which is connecting the gate terminal to three previous nodes (FIG. **6**C) for the PMOS transistors are simulated to obtain constant maximum efficiency contour plots as shown in FIG. **7**. Increasing the level of compensation leads to reduction in the threshold voltage which improves the forward-conduction but also increases the reverse leakage current. In the multipliers as shown in FIGS. **6**A and **6**C, during the positive input phase, transistor M_n is forward-biased. Since the gate terminals are connected to the previous node, V_{sg} when forward-biased is higher compared to that of the conventional diode-connected case with no threshold-voltage compensation which increases the ratio of output power in the forward region to the input power. However, when the transistor M_n is reverse-biased, the V_{sg} is higher compared to the conventional diode-connected case increasing the reverse leakage current of the reverse-biased transistor. This can also be explained by the efficiency contour plots of the hybrid scheme as seen from FIG. **7**. The contour plots are simulated for constant efficiency with different level of compensation and input power levels. As seen from FIG. **7**, though with the increase in the level of compensation the threshold voltage reduces, the efficiency degrades at the same time which is due to the increased reverse leakage current. The simulated maximum PCE of 28% degrades to 11% from level-1 compensation to level-3 compensation respectively. Accordingly an adaptive scheme is proposed to control the threshold voltage and the reverse leakage current of the rectifying device dynamically to improve the PCE over a wide range of input power. Ideally, the threshold voltage of the rectifying device should be zero when the transistors are forward-biased while the threshold voltage should be high when the transistors are reverse-biased to prevent any leakage or the losses associated with it.

[0069] We propose an adaptive forward and backward threshold-voltage compensation scheme that use minimal additional circuitry to increase the threshold-voltage compensation when transistors are forward-biased and decrease the compensation voltage when they are reverse-biased. The PMOS transistors in the main rectification chain are back-compensated when forward-biased and forward-compensated when reverse-biased; increasing the forward-current and reducing the reverse leakage current dynamically.

[0070] Proposed Adaptive Threshold Voltage Compensation

[0071] The hybrid forward and back-compensated topology described above can be made adaptive using an auxiliary block controlling the gate-source voltage of the MOS transistors in the main rectification chain. The auxiliary structure may be realized using all PMOS transistors to allow for individual body biasing. Preferably the auxiliary blocks are designed using minimum number of PMOS transistors so that the power losses do not increase considerably due to the additional blocks. The controlling voltage of the transistors in the auxiliary chain is derived from the local node of the main rectification chain. Two possible implementation of the proposed adaptive threshold voltage compensation scheme are discussed in the following section, one using diode-connected PMOS transistors and the other solid-wired connection to adaptively adjust the level of the threshold-voltage compensation.

[0072] Using Diode-Connected Transistor for Back-Compensation

[0073] FIG. **9**A shows the hybrid forward and back-threshold compensated rectifier using diode-connected transistors for back-compensation. The back-compensation reduces the threshold voltage when the transistors are forward-biased and forward-compensation reduces the reverse leakage current when reverse-biased with the control signal derived from the local node. In the embodiment shown the last transistor M_{n+1} is left uncompensated to reduce the leakage. During the negative input phase, in which the transistor M_n is forward-biased, the transistor M_n is back-compensated by the diode-connected transistor M_{na} while the V_{SG} terminal voltage for the transistor M_{nb} lies below its threshold voltage resulting in transistor M_{nb} turned OFF. In comparison to the embodiment shown in FIG. **6**B, diode-connected transistor M_{na} lies on the line connecting to the gate of transistor M_n. Transistor M_{nb} lies on a different line not corresponding to a line in FIG. **6**B, providing a forward connection for the gate of transistor M_n when transistor M_{nb} is active. In the embodiment shown in FIG. **9**A p-type transistors are used, but n-type could also be used. Additional transistors of the opposite type may be used at one end as in FIG. **6**B. The back-compensation for the transistor M_n in the main chain enhances the forward current. During the positive input phase, in which the transistor M_n is reverse-biased, the V_{SG} terminal for transistor M_{nb} is enough to turn ON the forward connection thus reducing the V_{SG} bias of the transistor M_n to zero resulting in a reduced leakage current. FIG. **10**A shows the efficiency contour plot for the adaptive diode-connected scheme as a function of width and the number of stages of the rectifier. Generating contour plots are an effective way to optimize the number of stages and the width of the transistors to maximize the PCE while obtaining the required voltage. Twelve-stage of voltage doubler design equivalent to 24-stage rectifier with transistor width of 11 μm gives the highest efficiency contour. The width of the diode-connected transistor in the auxiliary chain should be comparable to the width of the transistors in the main rectification chain so that it provides low forward-resistance when the transistors are conducting. In an embodiment, the width of the diode connected transistor in the auxiliary chain may be 8 μm. The auxiliary transistor used for forward compensation to control the reverse-leakage is selected in an embodiment to be 480 nm, an order of magnitude smaller than the diode-connected transistor to minimize their power consumption and reduce the parasitic at the nodes of the main rectification chain. Larger transistor widths are avoided to reduce the parasitic at the nodes of the main rectification chain.

[0074] Also, for the diode-connected scheme, the auxiliary block is added for every alternate transistor starting from the later stages and adding the blocks towards the initial stages. The maximum PCE increases with the addition of the adaptive auxiliary blocks.

[0075] Using Solid Connection for Back-Compensation

[0076] FIG. **9**B shows the adaptive hybrid topology using solid wired connection instead of the diode-connected transistor for reducing the threshold voltage. When the transistors are in the conduction phase (forward biased) they are back-compensated with solid wired connection instead of the diode-connected transistors which prevents the forward-losses associated with it. In the embodiment of FIG. **9**B, as compared to FIG. **9**A, the transistors M_{na}, $M_{n-1})_a$ etc. are omitted and replaced by a solid wire connection as in FIG. **6**B, but the transistors M_{nb}, $M_{(n-1)b}$ etc. are retained. In the embodiment shown in FIG. **9**A p-type transistors are used, but n-type could also be used. Additional transistors of the opposite type may be used at one end as in FIG. **6**B. When the transistor M_n is reverse-biased (not in the conduction phase), the V_{sg} terminal voltage for the auxiliary transistor M_{nb} is large to turn ON the forward-connection and reduce the source-gate bias of transistor M_n. This decreases the reverse leakage current greatly. FIG. **10**B shows an efficiency contour plot for the solid-wired scheme as a function of width and the number of stages of the rectifier. Twelve stages of doubler design equivalent to 24-stage rectifier with transistor width of 10 μm gives the maximum efficiency contour. The efficiency contour plot for the solid-connection follows similar trend as the diode-connected one. With the increase in the width of the transistors while maintaining the number of stages, the efficiency initially increases and then degrades due to the increased parasitic losses. Similarly, when the width of the transistor is kept constant and the number of stages is increased, the efficiency initially increases and then degrades as more number of stages is added due to the increased power loss with additional stages. Coupling capacitor value of 4 pF is selected as it has a very modest impact on the rectifier's efficiency.

[0077] Further embodiments are shown in FIG. **9**C and FIG. **9**D. The embodiment of FIG. **9**C operates in the same way as the embodiment of FIG. **9**B but uses n-type transistors instead of p-type. Accordingly, the solid wired connections to the gates of the transistors in the main chain are to the right instead of to the left. FIG. **9**D is an embodiment in which the connections to the gates of the transistors of the main chain are each controlled by two transistors. However, unlike in FIG. **9**A, one of these two transistors is p-type and the other is n-type. This allows the gates of these two transistors to be controlled by the same voltage, here using a line connecting to the junction to the right of the corresponding main transistor, and have at most one of the transistors ON at any given point in the input cycle. In addition, the transistors in the main chain are n-type in FIG. **9**D, whereas the transistors of the main chain are p-type in FIG. **9**A. However, either of the embodiments of FIG. **9**A or FIG. **9**D could use n-type or p-type transistors in the main chain, with corresponding changes to the direction of connections as seen in the differences between FIG. **9**B and FIG. **9**C. FIGS. **9**C and **9**D don't show the additional transistor at the end of the rectifier that is shown as M_{n+1} in FIGS. **9**A and **9**B, but such an additional transistor may also be present in these figures. The additional transistor can be p-type or n-type.

[0078] To investigate the effectiveness of the adaptive blocks in reducing the leakage current, leakage current as a function of input power is plotted as shown in FIG. **11**A. The leakage current is simulated for the last transistor with a 1 MΩ load for different input power levels. As shown in FIG. **11**A, comparing the schemes i.e. hybrid, adaptive solid and adaptive diode-connected for power levels of 1 μW-100 μW and at an operating frequency of 915 MHz, the reverse leakage current is maximum for the hybrid scheme and increases with the input power. At an input power of 105 μW, the leakage current is 12 nA. The adaptive solid and the adaptive diode-connected scheme have an auxiliary transistor to control the reverse leakage current. At an input power of 1 μW, the auxiliary transistor does not have enough input power to turn ON and provide the required forward-compensation. Hence the leakage current is comparable with the hybrid scheme. At 1 μW (−30 dBm), the output transistor's leakage current is 6.96 nA for the adaptive solid scheme and 7.56 nA for the adaptive diode-connected scheme with a 1 MΩ load. As the input power increases, the leakage current for the adaptive scheme is drastically reduced as seen in FIG. **11**A. Also, the reverse leakage current for the adaptive schemes is relatively constant with increase in the input power. The leakage current also depends on the load resistance and increases with decrease in the load resistance. Another performance measuring parameter we have defined is the current transfer ratio which is the ratio of the forward-current to the reverse leakage current. FIG. **11**B shows the current transfer ratio as a function of input power. The current transfer ratio at an input power of 1 μW (−30 dBm) for the hybrid scheme is 270, for the adaptive solid scheme is 140 and for the adaptive diode-connected one is 108. The current transfer ratio for the adaptive solid scheme increases rapidly and outperforms the hybrid scheme from 2 μW (−27 dBm) while for the adaptive diode-connected one, the current transfer ratio intersects the hybrid curve at 11 μW. The current transfer ratio for the hybrid scheme initially increases with the input power and saturates to approximately 1500 at 100 μW of input power. The current transfer ratio for the adaptive solid scheme rapidly increases with the input power. At an input power of 90 μW, the current transfer ratio for the adaptive solid scheme is 9000 as shown in FIG. **11**B. The current transfer ratio for the adaptive diode-connected scheme is 4000 at 97 μW of input power. The current transfer ratio for the adaptive-solid scheme at an input power of 100 μW (−10 dBm) is 6 times while for the diode-connected one is 2.5 times better than the hybrid scheme.

[0079] The proposed adaptive scheme is effective in increasing the PCE with the addition of auxiliary adaptive blocks. The increase in the PCE with the addition of the adaptive auxiliary blocks for the adaptive diode-connected scheme is shown in FIG. **12**A. With the addition of the auxiliary block the maximum PCE increases to 12%. The auxiliary block is added for every alternate transistor. However, the additional power consumed by the auxiliary diode-connected transistor when the rectifying device in the main rectification chain is forward-biased prevents the scheme from achieving higher PCEs. Unlike the adaptive diode-connected scheme, the auxiliary adaptive block is added to all the transistors for the adaptive solid scheme. Except for the first and the last stage, all the transistors for the solid adaptive scheme have the adaptive blocks. The additional power consumption and the parasitic capacitance introduced by the auxiliary chain are much lower than the former circuit as the solid-connected scheme uses only one transistor of width 480 nm per adaptive block. Hence the PCE is relatively higher at extremely low power levels. As seen from FIG. **12**B, with the addition of adaptive blocks, the efficiency increases. FIG. **12**B shows the improvement in PCE of the rectifier with the addition of auxiliary block. The maximum PCE reaches to 33.5% when the number of adaptive blocks is 20, a figure much higher than the adaptive diode-connected scheme which has a maximum PCE of 12%. The PCE and the output voltage performance at a relatively higher power level 0 dBm to −20 dBm is much better compared with only the hybrid scheme.

[0080] Impedance Matching Technique

[0081] The overall PCE of the RF energy harvesting system can be improved by increasing the passive voltage amplification due to the matching network, which increases the overall voltage at the input of the rectifier. The rectifier is modeled as $R_{rec}-jX_{rec}$ where R_{rec} is the real part of the rectifier's impedance and X_{rec} is the imaginary part. An impedance matching circuit is designed to match it to 50Ω as shown in FIG. **13**.

[0082] The input capacitance is mainly associated with the parasitic capacitance of the transistors and the layout. As the number of stages increases, the input resistance decreases while the parasitic capacitance increases. Increase in the value of load current also decreases the input resistance. The major factor contributing to increase in load current is lower load resistance. Other factors affecting the input impedance is the aspect ratio (W/L) of the transistors, input power level. Increase in the aspect ratio, increases the parasitic capacitance whereas decreases the input resistance. At the output side, the rectifier can be modeled by a voltage source and an output resistance. Thus the non-linear characteristic of the rectifier circuit makes it difficult to analyze them. The input impedance of the rectifier can be assumed to be constant only when small signal input is applied. In this case, the transient signal is a large signal with a capacitive component at the input causing a phase difference component ϕ to appear. The derivation in appendix though considers the reactive impedance still assumes the linear VI relationship. In real case, the VI relationship is non-linear and the input resistance is to be found using CAD tools.

[0083] Experimental Results—Hybrid Scheme

[0084] Three rectifiers, named as "efficiency", "voltage" and "1-stage PMOS doubler" are designed and fabricated in a 0.13 μm 8-metal CMOS process. The active die areas for efficiency circuit, voltage circuit and the 1-stage PMOS doubler test circuit are 230 μm×810 μm, 230 μm×1050 μm and 160 μm×70 μm respectively. The chip is wire-bonded onto PCB board with FR4 substrate and tested with Agilent MXG-N5181 signal generator at a frequency of 915 MHz using a single-tone sinusoidal signal. The receiver power is calculated by finding the average power at the input of the rectifier. The performance of the designed efficiency and voltage circuit is measured for a range of input power levels.

[0085] Output DC voltage was measured for different peak-to-peak input voltages. For a 1 MΩ load, an input voltage of 170 mV results in 2.4 V and 2.8 V for efficiency and voltage circuit, respectively. The voltage multiplication ratio (VMR) which is the ratio of DC voltage to the peak-to-peak input voltage is 14 and 17 for efficiency and voltage circuit respectively. A 220 mV signal results in 3.1 V for efficiency circuit and 4.0 V for voltage circuit. Similarly for a 5 MΩ load, an output of 2.7 V (VMR=16) for efficiency circuit and 3.0 V (VMR=18) for voltage circuit was measured at an input peak-to-peak voltage of 170 mV. Thus, voltage circuit which has a higher level of compensation than efficiency circuit has a lower input voltage requirement.

[0086] Harvested power was measured for different received powers. From the results, it was observed that at low power-level, the harvested power has a higher dependence on load current. For a 1 MΩ load at power levels greater than −30 dBm, the rate of decay in the harvested power curve is higher than the 5 MΩ load. The roll-off in the harvested power for a 1 MΩ load starts at about −20 dBm while the roll-off point for a 5 MΩ load is approximately −30 dBm. Even for voltage circuit, the rate of decay in the harvested power curve is greater for a 1 MΩ load compared to a 5 MΩ load. A lower load value has a higher current requirement. The performance of both the circuits in terms of roll-off is similar for the same load value. The designed efficiency and voltage circuit outperforms the circuit in Papotto et al. especially at low power levels. The efficiency circuit delivers an output power of 4.7 μW at an input power of −16.8 dBm (20.9 μW) when loaded by 1 MΩ. With a 5 MΩ load, the output power is 1 μW for an input power of −17.5 dBm (17.7 μW). An output power of 3.4 μW at an input power of −14.8 dBm (33.1 μW) for a 1 MΩ load is supplied by voltage circuit. A graph of the measurements was found to be in close agreement with the simulation results.

[0087] Power efficiency was measured for different received power levels. The measured and the simulated power conversion efficiency for efficiency and voltage circuit for different load resistance values are further compared. The efficiency comparison is done while de-embedding the input reflections in Papotto et al. The output DC voltage was also measured for the efficiency and voltage circuits for different load resistance values. The PCE is optimized for low power levels. When loaded by 1 MΩ, efficiency circuit attains a maximum measured PCE of 22.6% at −16.8 dBm (20.9 μW) while delivering 2.2 V to the output. A maximum measured PCE of 21.6% is obtained by efficiency circuit while producing an output voltage of 1.1 V at an input power of −26.5 dBm (2.23 μW) for a 5 MΩ load. At an input power level of −14.8 dBm (33.1 μW), voltage circuit achieves a maximum measured PCE of 10.2% for a 1 MΩ load while delivering 1.8 V. Due to a lower load current requirement for a 5 MΩ load, the output voltage is higher compared to a 1 MΩ load. At an input power of −22.5 dBm (5.6 μW), voltage circuit has a measured output DC voltage of 1 V while efficiency circuit has a measured output DC voltage of 1.8 V at −24 dBm (4 μW) for a 5 MΩ load.

[0088] Experimental Results—Adaptive Scheme

[0089] Three RF-DC power converters named as "adaptive solid," "adaptive diode-connected" and the "hybrid" circuits were designed and fabricated side by side in a 0.13 μm metal CMOS process with eight layers of metallization. The active die areas for adaptive solid and adaptive diode-connected is 0.25 mm^2 and hybrid circuit is 0.15 mm^2. The chip is wire-bonded onto a 2-layer FR-4 PCB board and tested with Agilent MXG-N5181 signal generator using frequency modulated continuous signal in the 902-928 MHz industrial, scientific and medical (ISM) band. An off-chip L-section impedance matching network is implemented on the PCB to convert the RF-DC power converter's input impedance to 50Ω. The output DC voltage was obtained with an oscilloscope or a digital multimeter. The measured and the simulated PCE for the adaptive and the hybrid scheme were compared for a load resistance of 1 MΩ at different input power levels. The output DC voltage was measured for the adaptive and the hybrid scheme for a load resistance of 1 MΩ. The simulation is performed at a frequency of 915 MHz which is the center frequency for the 902-928 MHz ISM band. The adaptive RF-DC power converters are designed to provide high PCE and a large output DC voltage for input power levels of 1 μW-100 μW (−30 dBm to −10 dBm). At larger input power, even with lower PCE the available output power is large hence designing for high input power levels is not so crucial. The adaptive solid scheme attains a maximum PCE of 32% at an input power of 32 μW (−15 dBm) with an output DC voltage of 3.2 V for a 1 MΩ load. For the input power of 32 μW and 1 MΩ load, the hybrid scheme has a PCE of 18% and delivers 2.6 V to the output. The adaptive diode-connected scheme has a maximum PCE of 11.3% at an input power of 118 μW while delivering 3.7 V to the output. The additional power consumed by the auxiliary diode-connected transistor when the rectifying device in the main rectification chain is forward-biased prevents the adaptive diode-connected scheme from achieving higher PCEs. The PCE was measured for different input power for the adaptive solid scheme at different load resistances. The output DC voltage for the adaptive solid scheme was also measured as a function of input power for different load resistances. As the load resistance decreases, the peak conversion efficiency curve shifts towards similar efficiencies at higher input power. The maximum measured PCE is 33.4% for a load resistance of 500 kΩ load at an input power of 83 μW. The PCE for a 500 kΩ load is larger than a 1 MΩ load for input power levels greater than 50 μW (−13 dBm). The peak power conversion efficiency curve is a function of the load resistance and can provide peak efficiency at a much lower power levels for larger load resistances. With decrease in load resistance, the circuit provides a smaller output voltage than with the high load resistance due to the low load current requirement at high load resistances. The hybrid scheme provides a larger output voltage compared to the adaptive schemes for input power levels lesser than 15 μW. The adaptive scheme outperforms the hybrid scheme once the power-up threshold-requirement is met. A DC output voltage of 3.2 V is obtained at an input power of 64 μW (−12 dBm) for a 500 kΩ load.

[0090] The harvested power was measured as a function of input power for the adaptive and the hybrid scheme. When loaded by 1 MΩ, an output power of 10 μW is harvested with an input power of 250 μW (−6 dBm) for the hybrid scheme while the adaptive solid scheme harvests 10 μW with only 30 μW (−15.3 dBm) of input power. With a load resistance of 500 kΩ, 10 μW of output power is harvested at an input power of 42 μW (−13.8 dBm). An output power of 20 μW is harvested at an input power of 64 μW (−12 dBm) for a 500 kΩ load using adaptive solid scheme. For a 1 MΩ load, at larger input power, the PCE degrades much more rapidly compared to a 500 kΩ load. For a 1 MΩ load, 20 μW of power is harvested by the adaptive solid scheme at 164 μW (−7.9 dBm). Even with an input power of few milliwatts, the hybrid scheme is not effective in harvesting 20 μW of output power.

[0091] The adaptive scheme is highly effective when the input power is above 10 μW (−20 dBm) and a large output voltage (more than 1.5 V) is desired. The performance of the adaptive solid scheme is similar to the hybrid scheme for power levels of 1-10 μW (−30 dBm to −20 dBm). The sensitivity of the RF-DC power converter for obtaining an output voltage of 1 V with a 1 MΩ load for the adaptive solid scheme is 8.9 μW (−20.5 dBm). The sensitivity of the circuit using the hybrid scheme is 6.9 μW (−21.6 dBm). The adaptive diode-connected scheme gives similar performance as the adaptive solid scheme at input power levels greater than 100 μW (−10 dBm). For low power applications, the adaptive solid scheme should be preferred over the adaptive diode-connected scheme.

[0092] The forgoing description pertains to circuitry using MOSFET enhancement-mode transistors. Nothing in the description should be taken to exclude using other types of transistors with corresponding changes to the circuitry that would be obvious to a person skilled in the art.

[0093] Immaterial modifications may be made to the embodiments described here without departing from what is covered by the claims.

[0094] In the claims, the word “comprising” is used in its inclusive sense and does not exclude other elements being present. The indefinite articles “a” and “an” before a claim feature do not exclude more than one of the feature being present. Each one of the individual features described here may be used in one or more embodiments and is not, by virtue only of being described here, to be construed as essential to all embodiments as defined by the claims.

APPENDIX

[0095] In section II, the average input power was suggested consisting of real and imaginary parts.

$$V = V_{in}\sin\omega t,\ I = I_{in}(\sin\omega t - \phi)$$

$$P_{mean} = \frac{1}{T_2 - T_1}\int_{T_1}^{T_2} V_{in}\sin\omega t \cdot I_{in}(\sin\omega t - \phi)dt$$

$$Z_{in} = \frac{V_{in}^2}{2P_{mean}} \cdot \cos\phi + \frac{V_{in}^2}{4P_{mean}} \cdot \frac{\sin[2\omega(T_2 - T_1) - \phi]}{\omega(T_2 - T_1)}$$

[0096] Z_{in} consists of real and imaginary component. Equating the imaginary component to zero by considering the phase difference $\phi=0$.

$$R_{in} = \frac{V_{in}^2}{2P_{mean}},\ C_{in} = \frac{4P_{mean}(T_2 - T_1)}{V_{in}^2\sin[2\omega(T_2 - T_1) - \phi]}$$

1. A power conversion circuit comprising:

a first input line and a second input line, the first and second input lines configured to receive an alternating voltage differential between the first and second input lines;

a multi-stage rectifier comprising transistors arranged in series, each transistor having a gate, a source and a drain, adjacent transistors of the series being connected so that for adjacent p-type transistors the drain of the left p-type transistor is connected to the right adjacent source of the right p-type transistor and source of the right p-type transistor is connected to the left adjacent drain of the left p-type transistor, for adjacent n-type transistors the source of the left n-type transistor is connected to the right adjacent drain of the right n-type transistor and drain of the right n-type transistor is connected to the left adjacent source of the left n-type transistor, for a p-type transistor adjacent to an n-type transistor the source of the right p-type transistor is connected to the source of the left adjacent n-type transistor and drain of the left p-type transistor is connected to the drain of the right adjacent n-type transistor to form a junction, each junction being connected to one of the first input line and the second input line via a capacitor, with adjacent junctions having one junction of the adjacent junctions connected to the first input line and the other junction of the adjacent junctions connected to the second input line;

the gate of each transistor of the multi-stage rectifier being connected to a respective junction that is not a junction formed by the connection of that transistor to an adjacent transistor but a junction in the previous stage for the p-type transistor or later stage for the n-type transistor, at least one of the transistor in the multi-stage rectifier being p-type and at least one being n-type.

2. The power conversion circuit of claim **1** further comprising an auxiliary chain of p-type transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to a p-type transistor of the multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the previous stage junction of the main chain which is N transistors away from the respective transistor, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of the later stage transistor in the main chain.

3. The power conversion circuit of claim **1** further comprising an auxiliary chain of n-type transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to an n-type transistor of the multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the later stage junction of the main chain which is N transistors away from the respective transistor, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of the previous stage transistor in the main chain.

4. An auxiliary chain of transistors, each auxiliary transistor having a gate, a source and a drain, each transistor of the auxiliary chain being connected to a respective transistor of a main chain of a multi-stage rectifier in the main chain, so that the gate of the respective auxiliary transistor is connected to the source of the respective transistor in the main chain, the source of the respective auxiliary transistor is connected to the gate of the transistor in the main chain and also connected to the later stage junction of the main chain which is N transistors away from the respective transistor in the case that the respective transistor is n-type, or to the earlier stage junction of the main chain which is N transistors away from the respective transistor in the case that the respective transistor is p-type, and the drain of the respective auxiliary transistor is connected to the drain of the respective transistor or to the junction of a previous stage transistor in the main chain, in the case that the respective transistor is n-type, or to the junction of a later stage transistor in the main chain, in the case that the respective transistor is p-type.

5. The power conversion circuit of claim **4** in which the transistors of the main chain and auxiliary chain are n-type and further comprising a p-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages, such that the gate of the additional p-type auxiliary transistor is connected to the gate of the n-type auxiliary transistor and the source of the n-type and p-type auxiliary transistors are connected, and the drain of the p-type auxiliary transistors is connected to junction of the main chain which is at 'N' later stages from the respective transistor.

6. The power conversion circuit of claim **4** in which the transistors of the main chain and auxiliary chain are p-type and further comprising an n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of earlier stages, such that the gate of the additional n-type auxiliary transistor is connected to the gate of the p-type auxiliary transistor and the source of the n-type and p-type auxiliary transistors are connected, and the drain of the n-type auxiliary transistors is connected to junction of the main chain which is at 'N' earlier stages from the respective transistor.

7. The power conversion circuit of claim **2** further comprising a diode connected transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of previous stages which is N transistors away from the respective transistor.

8. The power conversion circuit of claim **3** further comprising a diode connected transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages which is N transistors away from the respective transistor.

9. The power conversion circuit of claim **4** further comprising a diode connected p-type or n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of later stages which is N transistors away from the respective transistor.

10. The power conversion circuit of claim **4** further comprising a diode connected p-type or n-type transistor on a line connecting the gate of each transistor in the main chain of the multistage rectifier to the junction of earlier stages which is N transistors away from the respective transistor.

11. The power conversion circuit of claim **1** further comprising an additional transistor connected in series with the multistage rectifier, the additional transistor having a gate, a source and a drain, the gate of the additional transistor being connected to the drain of the additional transistor.

12. The power conversion circuit of claim **1** in which the gate of each transistor in the main chain is connected to the junction of previous stages for p-type transistor and later stages for n-type transistor.

13. The power conversion circuit of claim **12** in which N of the transistors in the multistage rectifier arranged in series are n-type and all but N of the transistors in multistage rectifier arranged in series are p-type.

14. The power conversion circuit of claim **1** in which the second input line is grounded.

15. The power conversion circuit of claim **1** in which the body terminal of each p-type transistor is connected to the respective drain and the body terminal of each n-type transistor is either grounded or connected to the respective drain terminal.

(57) **ABSTRACT**

A device includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a splitter/coupler adapted to split the received RF signal, a receiver adapted to demodulate the data from a first portion of the RF signal, and a power recovery unit adapted to convert to a DC power a second portion of the RF signal. The splitter/coupler is optionally adjustable to split the RF signal in accordance with a value that may be representative of a number of factors, such as the target data rate, the DC power requirement of the device, and the like. The device optionally includes a switch and/or a power combiner adapted to deliver all the received RF power to the receiver depending on any number of operation conditions of the device or the device's distance from an RF transmitting device.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] The present application is a continuation-in-part of application Ser. No. 14/078,489, filed Nov. 12, 2013, entitled "Smart RF Lensing: Efficient, Dynamic And Mobile Wireless Power Transfer" which claims benefit under 35 §U.S.C 119(e) of U.S. Provisional Patent Application No. 61/724,638, filed Nov. 9, 2012, entitled "Smart RF Lensing: Efficient, Dynamic And Mobile Wireless Power Transfer", the contents of which are incorporated herein by reference in its entirety.

[0002] The present application claims benefit under 35 §U.S.C 119(e) of U.S. Provisional Patent Application No. 62/222,106, filed Sep. 22, 2015, entitled "Smart RF Lensing: Efficient, Dynamic And Mobile Wireless Power Transfer", the content of which is incorporated herein by reference in its entirety.

[0003] The present application is related to the following US applications:

[0004] application Ser. No. 14/552,249, filed Nov. 24, 2014, entitled "Active CMOS Recovery Units For Wireless Power Transmission";

[0005] application Ser. No. 14/552,414, filed Nov. 24, 2014, entitled "Generator Unit For Wireless Power Transfer"; and

[0006] application Ser. No. 14/830,692, filed Aug. 19, 2015, entitled "Wireless Power Transfer";

the contents of all of which applications are incorporated herein by reference in their entirety.

BACKGROUND OF THE INVENTION

[0007] The present invention relates to wireless communication, and more particularly to wireless power and data transfer.

BACKGROUND OF THE INVENTION

[0008] Electrical energy used in powering electronic devices comes predominantly from wired sources. Conventional wireless power transfer relies on magnetic inductive effect between two coils placed in close proximity of one another. To increase its efficiency, the coil size is selected to be less than the wavelength of the radiated electromagnetic wave. The transferred power diminishes strongly as the distance between the source and the charging device is increased.

BRIEF SUMMARY OF THE INVENTION

[0009] An RF lens, in accordance with one embodiment of the present invention, includes, in part, a multitude of radiators adapted to radiate electromagnetic waves to power a device positioned away from the RF lens. Each of the multitude of radiators operates at the same frequency. The phase of the electromagnetic wave radiated by each of the multitude of radiators is selected to be representative of the distance between that radiator and the device.

[0010] In one embodiment, the multitude of radiators are formed in an array. In one embodiment, the array is a one-dimensional array. In another embodiment, the array is a two-dimensional array. In one embodiment, the amplitudes of the electromagnetic waves radiated by the radiators is variable. In one embodiment, each of the multitude of radiators includes, in part, a variable delay element, a control circuit adapted to lock the phase or frequency of the electromagnetic wave radiated by that radiator to the phase or frequency of a reference signal, an amplifier, and an antenna.

[0011] In one embodiment, the multitude of radiators are formed in a first radiator tile adapted to receive a second radiator tile having disposed therein another multitude of radiators. In one embodiment, the RF lens is further adapted to track a position of the device. In one embodiment, each of a first subset of the radiators includes a circuit for receiving an electromagnetic wave transmitted by the device thus enabling the RF lens to determine the position of the device in accordance with the phases of the electromagnetic wave received by the first subset of the radiators.

[0012] In one embodiment, each of at least a first subset of the radiators includes a circuit for receiving an electromagnetic wave transmitted by the device thereby enabling the RF lens to determine a position of the device in accordance with a travel time of the electromagnetic wave from the device to each of the first subset of the radiators and a travel time of a response electromagnetic wave transmitted from the RF lens to the device. In one embodiment, the RF lens is formed in a semiconductor substrate.

[0013] A method of wirelessly powering a device, in accordance with one embodiment of the present invention, includes, in part, transmitting a multitude of electromagnetic waves having the same frequency from a multitude of radiators to the device, selecting a phase of each of the multitude of radiators in accordance with a distance between that radiator and the device, and charging the device using the electromagnetic waves received by the device.

[0014] In one embodiment, the method further includes, in part, forming the radiators in an array. In one embodiment, the radiators are formed in a one-dimensional array. In another embodiment, the radiators are formed in a two-dimensional array. In one embodiment, the method further includes, in part, varying the amplitude of the electromagnetic wave radiated by each of the radiators.

[0015] In one embodiment, each radiators includes, in part, a variable delay element, a controlled locked circuit adapted to lock the phase or the frequency of the electromagnetic wave radiated by the radiator to the phase or frequency of a reference signal, an amplifier, and an antenna. In one embodiment, the radiators are formed in a first radiator tile adapted to receive a second radiator tile having disposed therein another multitude of radiators.

[0016] In one embodiment, the method further includes, in part, tracking the position of the device. In one embodiment, the method further includes, in part, determining the position of the device in accordance with relative phases of an electromagnetic wave transmitted by the device and received by each of at least a subset of the radiators. In one embodiment, the method further includes, in part, determining the position of the device in accordance with a travel time of an electromagnetic wave transmitted by the device and received by each of at least a subset of the radiators, and further in accordance with a travel time of a response electromagnetic wave transmitted from the RF lens to the device. In one embodiment, the method further includes, in part, forming the RF lens in a semiconductor substrate.

[0017] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a splitter/coupler adapted to split the received RF signal into first and second portions, a receiver adapted to demodulate the data from the first portion of the received RF signal, and a power recovery unit adapted to convert the second portion of the RF signal to a DC power to power the device. In one embodiment, the splitter/coupler is an adjustable splitter/coupler

[0018] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a receiver adapted to demodulate the data from a first portion of the RF signal, a power recovery unit adapted to convert a second portion of the RF signal to a DC power to power the device, and a controller adapted to receive the RF signal from the antenna and generate the first and second portions of the RF signal in accordance with impedance values of the receiver and the power recovery unit.

[0019] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a switch adapted to receive the RF signal from the antenna, a power recovery unit adapted to convert the RF signal to a DC power to power the device when the switch is in a first position, and a receiver adapted to demodulate the data from the received RF signal when the switch is in a second position.

[0020] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a splitter/coupler adapted to split the received RF signal into first and second portions, a switch adapted to receive the second portion of the RF signal from the splitter/coupler, a power recovery unit adapted to convert the second portion of the RF signal to a DC power to power the device when the switch is in a first position, and a power combiner adapted to receive the first portion of the RF signal from the splitter/coupler and further to receive the second portion of the RF signal when the switch is in a second position, and a receiver adapted to demodulate the data from an output signal of the power combiner. In one embodiment, the device further includes a controller adapted to cause the switch to be in the first position when a power of the received RF signal is less than a first threshold value. In one embodiment, the device further includes a controller adapted to cause the switch to be in the first position when the device indicates that its DC power exceeds a second threshold value.

[0021] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a switch adapted to receive the RF signal from the antenna, a power combiner coupled to a first output terminal of the switch to receive the RF signal when the switch is in a first position, a splitter/coupler coupled to a second output terminal of the switch to receive the RF signal, when the switch is in a second position, to split the RF signal into a first portion and a second portion and deliver the first portion of the RF signal to the power combiner, a power recovery unit adapted to convert the first portion of the RF signal to a DC power to charge the device when the switch is in the second position, and a receiver adapted to demodulate the data from an output signal of the power combiner. In one embodiment, the device further includes, in part, a controller adapted to cause the switch to be in the first position when a power of the received RF signal is less than a threshold value. In yet another embodiment, the device further includes a controller adapted to cause the switch to be in the first position when the device indicates that its DC power exceeds a threshold value.

[0022] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a controller, an adjustable splitter/coupler adapted to split the received RF signal into first and second portions in accordance with a value the adjustable splitter/coupler receives from the controller, a receiver adapted to demodulate the data from the first portion of the RF signal, and a power recovery unit adapted to convert the second portion of the RF signal to a DC power to charge the device. In one embodiment, the value supplied by the controller is defined by a target data rate of the device. In another embodiment, the value supplied by the controller is defined by a DC power requirement of the device.

[0023] A method, in accordance with one embodiment of the present invention, includes, in part, receiving an RF signal that includes modulated data, splitting the received RF signal to first and second portions, demodulating the data from the first portion of the RF signal, and converting the second portion of the RF signal to a DC power.

[0024] A method, in accordance with one embodiment of the present invention, includes, in part, receiving an RF signal that includes modulated data, demodulating the data from a first portion of the received RF signal via a receiver, converting a second portion of the RF signal to a DC power via a power recovery unit, and generating the first and second portions of the RF signal in accordance with impedance values of the receiver and the power recovery unit.

[0025] A method, in accordance with one embodiment of the present invention, includes, in part, receiving an RF signal that includes modulated data, converting the RF signal to a DC power when a switch is in a first position, and demodulating the data from the received RF signal when the switch is in a second position.

[0026] A method, in accordance with one embodiment of the present invention, includes, in part, receiving an RF signal that includes modulated data, demodulating the data using either a first portion of the RF signal or the RF signal, and converting a second portion of the RF signal to a DC power when the first portion of the RF signal is used for demodulating the data. In one embodiment, the data is modulated using the RF signal when a power of the received RF signal is less than a first threshold value. In one embodiment, the data is demodulated using the RF signal when an indication is received that a battery charge exceeds a threshold value.

[0027] A device, in accordance with one embodiment of the present invention, includes, in part, an antenna adapted to receive an RF signal that includes modulated data, a controller, an adjustable splitter/coupler adapted to split the received RF signal into first and second portions in accordance with a value the adjustable splitter/coupler receives from the controller, a receiver adapted to demodulate the data from the first portion of the RF signal, and a power recovery unit adapted to convert the second portion of the RF signal to a DC power to charge the device. In one embodiment, the value supplied by the controller is defined by a target data rate of the device. In another embodiment, the value supplied by the controller is defined by a DC power requirement of the device.

[0028] A method, in accordance with one embodiment of the present invention, includes, in part, receiving an RF signal, splitting the received RF signal to first and second portions in accordance with a received value, demodulating the data from the first portion of the RF signal, and converting the second portion of the RF signal to a DC power. In one embodiment, the value is defined by a target data rate. In one embodiment, the value is defined by a DC power requirement.

DETAILED DESCRIPTION OF THE INVENTION

[0065] An RF lens, in accordance with one embodiment of the present invention, includes a multitude of radiators adapted to transmit radio frequency electromagnetic EM waves (hereinafter alternatively referred to as EM waves, or waves) whose phases and amplitudes are modulated so as to concentrate the radiated power in a small volume of space (hereinafter alternatively referred to as focus point or target zone) in order to power an electronic device positioned in that space. Accordingly, the waves emitted by the radiators are caused to interfere constructively at the focus point. Although the description below is provided with reference to wireless power transfer, the following embodiments of the present invention may be used to transfer any other kind of information wirelessly.

[0066] FIG. **1** shows a multitude of radiators, arranged in an array **100**, forming an RF lens, in accordance with one embodiment of the present invention. Array **100** is shown as including N radiators $\mathbf{10}_1$, $\mathbf{10}_2$, $\mathbf{10}_3$ . . . $\mathbf{10}_{N-1}$, $\mathbf{10}_N$ each adapted to radiate an EM wave whose amplitude and phase may be independently controlled in order to cause constructive interference of the radiated EM waves at a focus point where a device to be charged is located, where N is integer greater than 1. FIG. **2** is a side view of the array **100** when the relative phases of the waves generated by radiators $\mathbf{10}_i$ (i is an integer ranging from 1 to N) are selected so as to cause constructive interference between the waves to occur near region **102** where a device being wirelessly charged is positioned, i.e., the focus point. Region **102** is shown as being positioned at approximately distance d_1 from center **104** of array **100**. The distance between the array center and the focus point is alternatively referred to herein as the focal length. Although the following description of an RF lens is provided with reference to a one or two dimensional array of radiators, it is understood that an RF lens in accordance with the present invention may have any other arrangement of the radiators, such as a circular arrangement **1000** of radiators **202** as shown in FIG. **22**A, or the elliptical arrangement **1010** of radiators **202** shown in FIG. **22**B.

[0067] As seen from FIG. **2**, each radiator $\mathbf{10}_i$ is assumed to be positioned at distance y_i from center **104** of array **100**. The amplitude and phase of the wave radiated by radiator $\mathbf{10}_i$ are assumed to be represented by A_i and θ_i respectively. Assume further that the wavelength of the waves being radiated is represented by) λ. To cause the waves radiated by the radiators to interfere constructively in region **102** (i.e., the desired focus point), the following relationship is satisfied between various phases θ_i and distances y_i:

$$\theta_1 + \frac{2\pi}{\lambda}\sqrt{d_1^2 + y_1^2} = \theta_2 + \frac{2\pi}{\lambda}\sqrt{d_1^2 + y_2^2} = \cdots = \theta_N + \frac{2\pi}{\lambda}\sqrt{d_1^2 + y_N^2}$$

[0068] Since the phase of an RF signal may be accurately controlled, power radiated from multiple sources may be focused, in accordance with the present invention, onto a target zone where a device to be wirelessly charged is located. Furthermore, dynamic phase control enables the tracking of the device as it moves from its initial location. For example, as shown in FIG. **3**, if the device moves to a different position—along the focal plane—located at a distance d_2 from center point **104** of the array, in order to ensure that the target zone is also located at distance d_2, the phases of the sources may be adjusted in accordance with the following relationship:

$$\theta_1 + \frac{2\pi}{\lambda}\sqrt{d_2^2 + y_1^2} = \theta_2 + \frac{2\pi}{\lambda}\sqrt{d_2^2 + y_2^2} = \cdots = \theta_N + \frac{2\pi}{\lambda}\sqrt{d_2^2 + y_N^2} \qquad (1)$$

[0069] Referring to FIG. **4**, if the device moves to a different position away from the focal plane (e.g., to a different point along the y-axis) the radiators' phases are dynamically adjusted, as described below, so as to track and maintain the target zone focused on the device. Parameter y_c represents the y-component of the device's new position, as shown in FIG. **4**, from the focal plane of the array (i.e, the plane perpendicular to the y-axis and passing through center **104** of array **100**).

$$\begin{aligned}\theta_1 + \frac{2\pi}{\lambda}\sqrt{d_2^2 + (y_1 - y_c)^2} &= \\ \theta_2 + \frac{2\pi}{\lambda}\sqrt{d_2^2 + (y_2 - y_c)^2} &= \cdots = \theta_N + \frac{2\pi}{\lambda}\sqrt{d_2^2 + (y_N - y_c)^2}\end{aligned} \qquad (2)$$

[0070] The amount of power transferred is defined by the wavelength λ of the waves being radiated by the radiators, the array span or array aperture A as shown in FIG. **1**, and the focal length, i.e. (λF/A).

[0071] In one embodiment, the distance between each pair of radiators is of the order of the wavelength of the signal being radiated. For example, if the frequency of the radiated wave is 2.4 GHz (i.e., the wavelength is 12.5 cm), the distance between each two radiators may be a few tenths to a few tens of the wavelengths, that may vary depending on the application.

[0072] An RF lens, in accordance with the present invention, is operative to transfer power wirelessly in both near-field and far field regions. In the optical domain, a near field region is referred to as the Fresnel region and is defined as a region in which the focal length is of the order of the aperture size. In the optical domain, a far field region is referred to as the Fraunhofer region and is defined as a region in which the focal length (F) is substantially greater than ($2\ A^2/\lambda$).

[0073] To transfer power wirelessly to a device, in accordance with the present invention, the radiator phases are selected so as to account for differences in distances between the target point and the radiators. For example, assume that the focal length d_1 in FIG. **2** is of the order of the aperture size A. Therefore, since distances S_1, S_2, S_3 . . . S_N are different from one another, corresponding phases θ_1, θ_2, θ_3 . . . θ_N of radiators $\mathbf{10}_1$, $\mathbf{10}_2$, $\mathbf{10}_3$ . . . $\mathbf{10}_N$ are varied so as to satisfy expression (1), described above. The size of the focus point (approximately $\lambda F/A$) is relatively small for such regions because of the diffraction limited length.

[0074] A radiator array, in accordance with the present invention, is also operative to transfer power wirelessly to a target device in the far field region where the focal length is greater than ($2A^2/\lambda$). For such regions, the distances from the different array elements to the focus spot are assumed be to be the same. Accordingly, for such regions, $S_1=S_2=S_3$ . . . $=S_N$, and $\theta_1=\theta_2=\theta_3$ . . . $=\theta_N$. The size of the focus point is relatively larger for such regions and thus is more suitable for wireless charging of larger appliances.

[0075] FIG. **5** shows an RF lens **200**, in accordance with another embodiment of the present invention. RF lens **200** is shown as including a two dimensional array of radiators $\mathbf{202}_{i,j}$ arranged along rows and columns Although RF lens **200** is shown as including 121 radiators $\mathbf{202}_{i,j}$ disposed along 11 rows and 11 columns (integers i and j are indices ranging from 1 to 11) it is understood that an RF lens in accordance with embodiments of the present invention may have any number of radiators disposed along U rows and V columns, where U and V are integers greater one. In the following description, radiators $\mathbf{202}_{i,j}$ may be collectively or individually referred to as radiators **202**.

[0076] As described further blow, the array radiators are locked to a reference frequency, which may be a subharmonic (n=1, 2, 3 . . .) of the radiated frequency, or at the same frequency as the radiated frequency. The phase of the wave radiated by each radiator are controlled independently in order to enable the radiated waves to constructively interfere and concentrate their power onto a target zone within any region in space.

[0077] FIG. **6**A is a simplified block diagram of a radiator **202** disposed in RF lens **200**, in accordance with one embodiment of the present invention. As seen, radiator **202** is shown as including, in part, a programmable delay element (also referred to herein as phase modulator) **210**, a phase/frequency locked loop **212**, a power amplifier **214**, and an antenna **216**. Programmable delay element **210** is adapted to delay signal W_2 to generate signal W_3.

[0078] The delay between signals W_2 and W_3 is determined in accordance with control signal Ctrl applied to the delay element. In one embodiment, phase/frequency locked loop **212** receives signal W_1 as well as a reference clock signal having a frequency F_{ref} to generate signal W_2 whose frequency is locked to the reference frequency Ref. In another embodiment, signal W_2 generated by phase/frequency locked loop **212** has a frequency defined by a multiple of the reference frequency F_{ref}. Signal W_3 is amplified by power amplifier **214** and transmitted by antenna **216**. Accordingly and as described above, the phase of the signal radiated by each radiator **202** may be varied by an associated programmable delay element **210** disposed in the radiator.

[0079] FIG. **6**B is a simplified block diagram of a radiator **202** disposed in RF lens **200**, in accordance with another embodiment of the present invention. As seen, radiator **202** is shown as including, in part, a programmable delay element **210**, a phase/frequency locked loop **212**, a power amplifier **214**, and an antenna **216**. Programmable delay element **210** is adapted to delay the reference clock signal F_{ref} thereby to generate a delayed reference clock signal F_{ref_Delay}. The delay between signals F_{ref} and F_{ref_Delay} is determined in accordance with control signal Ctrl applied to the delay element **210**. Signal W_2 generated by phase/frequency locked loop **212** has a frequency locked to the frequency of signal F_{ref_Delay} or a multiple of the frequency of signal F_{ref_Delay}. In other embodiments (not shown), the delay element is disposed in and is part of phase/frequency locked loop **212**. In yet other embodiments (not shown), the radiators may not have an amplifier.

[0080] FIG. **7** shows a number of components of a device **300** adapted to be charged wirelessly, in accordance with one embodiment of the present invention. Device **300** is shown as including, in part, an antenna **302**, a rectifier **304**, and a regulator **306**. Antenna **302** receives the electromagnetic waves radiated by a radiator, in accordance with the present invention. Rectifier **304** is adapted to convert the received AC power to a DC power. Regulator **306** is adapted to regulate the voltage signal received from rectifier **304** and apply the regulated voltage to the device. High power transfer efficiency is obtained, in one embodiment, if the aperture area of the receiver antenna is comparable to the size of the target zone of the electromagnetic field. Since most of the radiated power is concentrated in a small volume forming the target zone, such a receiver antenna is thus optimized to ensure that most of the radiated power is utilized for charging up the device. In one embodiment, the device may be retro-fitted externally with components required for wireless charging. In another embodiment, existing circuitry present in the charging device, such as antenna, receivers, and the like, may be used to harness the power.

[0081] FIG. **8** is a schematic diagram of RF lens **200** wirelessly charging device **300**. In some embodiments, RF lens **200** wirelessly charges multiple devices concurrently. FIG. **9** shows RF lens **200** concurrently charging devices **310**, and **315** using focused waves of similar or different strengths. FIG. **10** shows RF lens **200** wireless charging mobile devices **320**, **325** and stationary device **330** all of which are assumed to be indoor.

[0082] FIG. **11**A shows computer-simulated electromagnetic field profiles generated by a one-dimensional RF lens at a distance 2 meters away from the RF lens having an array of 11 isotropic radiators. The beam profiles are generated for three different frequencies, namely 200 MHz (wavelength 150 cm), 800 MHz (wavelength 37.5 cm), and 2400 MHz (wavelength 12.50 cm). Since the distance between each pair of adjacent radiators of the RF lens is assumed to be 20 cm, the RF lens has an aperture of 2 m. Therefore, the wavelengths are of the order of aperture size and focal length of the radiator. FIG. **11**B is a simplified schematic view of such an RF lens **500** having 11 radiators **505***k* that are spaced 20 cm apart from one another, where K is an integer ranging from 1 to 11.

[0083] Plots **510**, **520** and **530** are computer simulations of the electromagnetic field profiles respectively for 200 MHz, 800 MHz, and 2400 signals radiated by radiator **500** when the relative phases of the various radiators are selected so as to account for the path differences from each of radiators $\mathbf{505}_k$ to the point located 2 meters away from radiator $\mathbf{505}_6$ in accordance with expression (1) above. For each of these profiles, the diffraction limited focus size is of the order of the wavelengths of the radiated signal. Plots **515**, **525** and **535** are computer simulations of the electromagnetic field profiles at a distance 2 meters away from the radiator array for 200 MHz, 800 MHz, and 2400 signals respectively when the phases of radiators **505**$_k$ were set equal to one another.

[0084] As seen from these profiles, for the larger wavelength having a frequency of 200 MHz (i.e, plots **510**, **515**), because the path differences from the individual radiators to the focus point are not substantially different, the difference between profiles **510** and **515** is relatively unpronounced. However, for each of 800 MHz and 2400 MHz frequencies, the EM confinement (focus) is substantially more when the relative phases of the various radiators are selected so as to account for the path differences from the radiators **505**$_k$ to the focus point than when radiator phases are set equal to one another. Although the above examples are provided with reference to operating frequencies of 200 MHz, 800 MHz, and 2400 MHz, it is understood that the embodiments of the present may be used in any other operating frequency, such as 5.8 GHz, 10 GHz, and 24 GHz.

[0085] FIG. **12** shows the variations in computer simulated electromagnetic field profiles generated by RF lens **500**—at a distance of 2 meters away from the RF lens—as a function of the spacing between each adjacent pair of radiators. The RF lens is assumed to operate at a frequency of 2400 MHz. Plots **610**, **620**, and **630** are computer simulations of the field profiles generated respectively for radiator spacings of 5 cm, 10 cm, and 20 cm after selecting the relative phases of the various radiators to account for the path differences from various radiators **505**$_k$ to the point 2 meters away from the RF lens, in accordance with expression (1) above. Plots **615**, **625**, and **650** are computer simulations of the field profiles generated respectively for radiator spacings of 5 cm, 10 cm, and 20 cm assuming all radiators disposed in RF lens **500** have equal phases. As is seen from these plots, as the distance between the radiators increases—thus resulting in a larger aperture size—the EM confinement also increases thereby resulting in a smaller focus point.

[0086] FIG. **13**A is the computer simulation of the EM profile of an RF lens at a distance 3 meters away from an RF lens having disposed therein a two-dimensional array of Hertzian dipoles operating at a frequency of 900 MHz, such as RF lens **200** shown in FIG. **5**. The spacing between the dipole radiators are assumed to be 30 cm. The relative phases of the radiators were selected so as to account for the path differences from the radiators to the focal point, assumed to be located 3 meters away from the RF lens. In other words, the relative phases of the radiators is selected to provide the RF lens with a focal length of approximately 3 meters. The scale used in generating FIG. **13**A is −15 dB to 0 dB. FIG. **13**B shows the EM profile of FIG. **13**A using a scale of −45 dB to 0 dB.

[0087] FIG. **14**A is the computer simulation of the EM profile of the RF lens of FIGS. **13**A/**13**B at a distance 2 meters away from the focal point, i.e., 5 meters away from the RF lens. As is seen from FIG. **14**A, the radiated power is diffused over a larger area compared to those shown in FIGS. **13**A and **13**B. The scale used in generating FIG. **14**A is −15 dB to 0 dB. FIG. **14**B shows the EM profile of FIG. **14**A using a scale of −45 dB to 0 dB.

[0088] FIG. **15**A is the computer simulation of the EM profile of an RF lens at a distance 3 meters away from the RF lens having disposed therein a two-dimensional array of Hertzian dipoles operating at a frequency of 900 MHz. The spacing between the dipole radiators are assumed to be 30 cm. The relative phases of the radiators are selected so as to account for the path differences from the radiators to the focal point, assumed to be located 3 meters away from the RF lens and at an offset of 1.5 m from the focal plane of the RF lens, i.e., the focus point has a y-coordinate of 1.5 meters from the focal plane (see FIG. **4**). The scale used in generating FIG. **15**A is −15 dB to 0. FIG. **15**B shows the EM profile of FIG. **15**A using a scale of −45 dB to 0 dB.

[0089] FIG. **16**A is the computer simulation of the EM profile of the RF lens of FIGS. **15**A/**15**B at a distance 2 meters away from the focal point, i.e., 5 meters away from the x-y plane of the RF lens. As is seen from FIG. **16**A, the radiated power is diffused over a larger area compared to that shown in FIG. **15**A. The scale used in generating FIG. **16**A is −15 dB to 0 dB. FIG. **16**B shows the EM profile of FIG. **16**A using a scale of −45 dB to 0 dB. The EM profiles shown in FIGS. **13**A, **13**B, **14**A, **14**B **15**A, **15**B, **16**A, **16**B demonstrate the versatility of an RF lens, in accordance with the present invention, in focusing power at any arbitrary point in 3D space.

[0090] In accordance with one aspect of the present invention, the size of the array forming an RF lens is configurable and may be varied by using radiator tiles each of which may include one or more radiators. FIG. **17**A shows an example of a radiator tile **700** having disposed therein four radiators **15**$_{11}$, **15**$_{12}$, **15**$_{21}$, and **15**$_{22}$. Although radiator tile **700** is shown as including four radiators, it is understood that a radiator tile, in accordance with one aspect of the present invention, may have fewer (e.g., one) or more than (e.g., 6) four radiators. FIG. **17**B shown an RF lens **800** initially formed using 7 radiator tiles, namely radiator tiles **700**$_{11}$, **700**$_{12}$, **700**$_{13}$, **700**$_{21}$, **700**$_{22}$, **700**$_{31}$, **700**$_{31}$—each of which is similar to radiator tile **700** shown in FIG. **17**A—and being provided with two more radiator tiles **700**$_{23}$ and **700**$_{33}$. Although not shown, it is understood that each radiator tile includes the electrical connections necessary to supply power to the radiators and deliver information from the radiators as necessary. In one embodiment, the radiators formed in the tiles are similar to radiator **202** shown in FIG. **6**.

[0091] In accordance with one aspect of the present invention, the RF lens is adapted to track the position of a mobile device in order to continue the charging process as the mobile device changes position. To achieve this, in one embodiment, a subset or all of the radiators forming the RF lens include a receiver. The device being charged also includes a transmitter adapted to radiate a continuous signal during the tracking phase. By detecting the relative differences between the phases (arrival times) of such a signal by at least three different receivers formed on the RF lens, the position of the charging device is tracked.

[0092] FIG. **18** is a simplified block diagram of a radiator **902** disposed in an RF lens, such as RF lens **200** shown in FIG. **5**, in accordance with one embodiment of the present invention. Radiator **902** is similar to radiator **202** shown in FIG. **6**, except that radiator **902** has a receiver amplifier and phase recovery circuit **218**, and a switch S_1. During power transfer, switch S_1 couples antenna **216** via node A to power amplifier **214** disposed in the transmit path. During tracking, switch S_1 couples antenna **216** via node B to receiver amplifier and phase recovery circuit **218** disposed in the receive path to receive the signal transmitted by the device being charged.

[0093] FIG. **19** shows a number of components of a device **900** adapted to be charged wirelessly, in accordance with one embodiment of the present invention. Device **900** is similar to device **300** shown in FIG. **7**, except that device **900** has a transmit amplifier **316**, and a switch S_2. During power transfer, switch S_2 couples antenna **302** via node D to rectifier **304** disposed in receive path. During tracking, switch S_2 couples antenna **302** via node C to transmit amplifier **316** to enable the transmission of a signal subsequently used by the RF lens to detect the position of device **300**. FIG. **20** shows RF lens **200** tracking device **900** by receiving the signal transmitted by device **900**.

[0094] A radiator, in accordance with any of the embodiments of the present invention, in addition to transferring RF power to a device wirelessly, may also wirelessly transfer modulated data to such a device. For example, a radiator, in accordance with the embodiments of the present invention, may operate as a wireless local area network (WLAN) router to direct signal power toward other such routers or receivers (WLAN or otherwise) to increase the received signal power by orders of magnitude and thereby increase the range, coverage and wireless data rates, as well as reduce the effect of multi-path propagation of the RF signal and power. Transferring wireless signal and/or power, in accordance with embodiments of the present invention and in conformity with any communication standards, such as WiFi, Zigbee, Bluetooth, GSM, GPRS, Edge, and UMTS, to a receiving device, and tracking the location of the device as it moves through physical space, greatly increases the range of the data link and achievable data rates.

[0095] Because the power levels required for data transmission are typically orders of magnitude lower than the power levels for wireless power transfer, in accordance with embodiments of the present invention, both power and data transmission may be performed concurrently. In other words, for any given amount of emitted power by a generation unit, in accordance with embodiments of the present invention, the range of wireless power transfer is smaller than the range for wireless data transmission. Therefore, a device that is in range for wireless power transfer, is also in range for wireless data transmission. Furthermore, the amount of power siphoned off in detecting the transmitted data signal is typically much smaller compared to the power available for concurrently powering the device. In addition, a device that may be charged wirelessly can also operate over the relatively narrow range of frequencies around the center frequency spanned by most signal modulation schemes used in data transmission.

[0096] FIG. **21**A is a simplified high-level block diagram of a device **750** (e.g., cellular phone, camera, wearable device, toy), in accordance with one embodiment of the present invention. Device **750** is shown as including, in part, an antenna **760**, a directional power splitter/coupler (alternatively referred to herein as coupler) **752**, a power recovery unit **754**, and a radio signal receiver/demodulator (alternatively referred to herein as receiver) **756**. Antenna **760** is adapted to receive a signal from a radiator or an array of radiators, as described for example above, and deliver the received signal to coupler **752**. The signal received by the antenna is a modulated signal that carries information/data as well as RF power, both of which are transmitted using the same frequency. Coupler **752** is adapted to transfer a first portion of the received RF signal to receiver **756** and a second portion of the received signal to power recovery unit **754**. Receiver **756** demodulates the received signal to recover the transmitted data. Power recovery unit **754** is adapted to convert the received RF signal to a DC power to power device **750** or charge device **750**'s battery. Although not shown, it is understood that device **750** may use filters and/or transistors instead of coupler **752** to distribute the received RF power between power recovery unit **754** and receiver **756**. U.S. application Ser. No. 14/552,249, filed Nov. 24, 2014, entitled “Active CMOS Recovery Units For Wireless Power Transmission”, the content of which is incorporated herein by reference in its entirety, describes in detail various embodiments of power recovery unit **754**. In one embodiment, directional coupler/splitter **752** is adjustable (via a controller not shown in FIG. **21**A) that can vary the split ratio so as to change the amount of power coupler/splitter **752** provides to receiver **756** relative to the power it provides to power recovery unit **754**.

[0097] FIG. **21**B is a simplified high-level block diagram of a device **755**, in accordance with one embodiment of the present invention. Device **750** is shown as including, in part, an antenna **760**, a controller **762**, a power recovery unit **754**, and a radio signal receiver/demodulator (hereinafter receiver) **756**. Antenna **760** is adapted to receive a signal from a radiator or an array of radiators, as described above, and deliver the received signal to controller **762**. Controller **762** is adapted to distribute the received RF power in accordance with an inverse ratio of the impedances of receiver **756** and power recovery unit **754**. Controller **762** may be further adapted to vary the impedances seen at its output terminals such that the output impedance having a closer value to the impedance seen at the input of controller **762** receives a higher amount of the received RF power.

[0098] FIG. **21**C is a simplified high-level block diagram of a device **760**, in accordance with another embodiment of the present invention. Device **760** is similar to device **750** except that device **760** uses a switch **764** in place of coupler **752**. When switch **764** is in position P_1, all of the received RF power is delivered to power recovery unit **754** thereby to charge device **760**. When switch **764** is in position P_2, all of the received RF power is delivered to receiver **756** to receive the transmitted data. For example, if device **760** is determined as being out-of-range for wireless power charging, switch **764** is placed in position P_2 to supply all of the received wireless power to receiver **756** to improve, e.g., its signal to noise ratio. Likewise, if device **760** is detected as being within range but requiring no additional charge, switch **764** is placed in position P_2 to supply all of the received wireless power to receiver **756**. If, for example, data reception is not of interest, switch **764** is placed in position P_1 to supply all of the received RF power to power recovery unit **754**.

[0099] For example, assume that an RF lens or a radiator array (a power generating unit) broadcasts an RF signal to determine if the received RF signal is strong enough to wirelessly charge a device receiving the RF signal. If the received RF signal is detected as not being strong enough to wirelessly charge the device, a controller (not shown in FIG. **21**C) controlling switch **764** may switch to radio receiving mode by placing switch **764** to position P_2. Once in the radio receiving mode, the device may then communicate with the radiator array to enable the radiator array to focus its RF power on the device. After the radiator array focuses its transmitted RF signal on device **760**, thereby causing the received RF signal to be sufficient for wireless charging, the controller may place switch **764** in position P_1 to enable power recovery unit **754** to charge device **760**. When device

760 is charged to a sufficient level, it may so inform the controller thus causing switch **764** to be placed in switch position P_2. It is understood that any number of conditions and criteria may be used to change the position of switch **764**.

[0100] FIG. **21**D is a simplified high-level block diagram of a device **765**, in accordance with another embodiment of the present invention. Device **765** is shown as including, in part, an antenna **760**, a coupler **752**, a switch **764**, a power combiner **758**, a power recovery unit **754**, and a receiver **756**. Antenna **760** is adapted to receive a modulated signal that carries information as well as RF power, both of which are transmitted using the same frequency. Coupler **752** is adapted to transfer a first portion of the received RF signal to power combiner **758**, and a second portion of the received signal to switch **764**. When switch **764** is position P_1, (i) the first portion of the power supplied by coupler **752** is delivered to receiver **756** via power combiner **758**, and (ii) the second portion of the power supplied by coupler **752** is delivered to power recovery unit **754** to wirelessly charge device **765**. Receiver **756** demodulates the received signal to recover the transmitted data.

[0101] When switch **764** is position P_2, power combiner **758** combines the first portion of the power it receives from coupler **752** with the second portion of power it receives from switch **764** and delivers the combined power to receiver **756**. Accordingly, in such embodiments, receiver **756** continues to receive the transmitted RF signal regardless of the switch position. For example, when the received RF power is detected as being below a threshold value, switch **764** is placed in position P_2 (via a controller not shown) so that all the received RF power is used for signal reception. When the received RF power is detected as being above a threshold value and/or device **765** requests to be charged, switch **764** is placed in position P_1 (via the controller) so that a relatively small fraction of the received RF power is used for signal detection by receiver **756**, and the remainder of the RF power is used by power recovery unit **754** to charge device **765**.

[0102] FIG. **21**E is a simplified high-level block diagram of a device **775**, in accordance with another embodiment of the present invention. Device **775** is shown as including, in part, an antenna **760**, a coupler **752**, a switch **764**, a power combiner **758**, a power recovery unit **754**, and a receiver **756**. Antenna **760** is adapted to receive a modulated signal that carries information/data as well as RF power, both of which are transmitted using the same frequency. Receiver **756** demodulates the received signal to recover the transmitted data.

[0103] When switch **764** is position P_2, the received RF signal is supplied to directional coupler **752**, which in turn, delivers (i) a first portion of the received power to receiver **756** via power combiner **758**, and (ii) a second portion of the received power to power recovery unit **754** for wirelessly charging device **775**. When switch **764** is in position P_1, substantially all of the received RF power is delivered to receiver **756** via power combiner **758**. Accordingly, device **775** is adapted to continuously deliver the RF signal to receiver **756**.

[0104] FIG. **21**F is a simplified high-level block diagram of a device **785**, in accordance with another embodiment of the present invention. Device **785** is shown as including, in part, an antenna **760**, an adjustable power splitter/coupler **782**, a control unit **762**, a power recovery unit **754**, and a receiver **756**. Antenna **760** is adapted to receive a modulated signal that carries information as well as RF power, both of which are transmitted using the same frequency. Adjustable power splitter/coupler **782** is adapted to split the RF signal it receives from antenna **760** into first and second portions in accordance with a split ratio adjustable power splitter/coupler **782** receives from control unit **762**. The split ratio supplied by control unit **762** may be defined by any number of factors, such as the target date rate set by receiver **756**, the DC power requested by the power recovery unit **754**, the power requested by receiver **756**, and the like.

[0105] Referring to FIGS. **21**A-**21**E, it is understood that power combiner **758** may be formed using any arrangement or configuration of active and/or passive devices capable of combining power from two or more sources. Typical examples include lossless power combiners such as coupled transmission lines, their lumped circuit equivalent using capacitors or inductors, magnetic transformers, and other circuits, as is well known. Directional coupler **752** may include coupled transmission lines, transformers and/or their lumped circuit equivalent. Switch **764** adapted to switch RF power may include pass gates, electronically tunable impedance networks, relays and the like, as is also well known.

[0106] In accordance with another embodiment of the present invention, a pulse based measurement technique is used to track the position of the mobile device. To achieve this, one or more radiators forming the RF lens transmit a pulse during the tracking phase. Upon receiving the pulse, the device being tracked sends a response which is received by the radiators disposed in the array. The travel time of the pulse from the RF lens to the device being tracked together with the travel times of the response pulse from the device being tracked to the RF lens is representative of the position of the device being tracked. In the presence of scatterers, the position of the device could be tracked using such estimation algorithms as maximum likelihood, or least-square, Kalman filtering, a combination of these techniques, or the like. The position of the device may also be determined and tracked using WiFi and GPS signals.

[0107] The presence of scattering objects, reflectors and absorbers may affect the RF lens' ability to focus the beam efficiently on the device undergoing wireless charging. For example, FIG. **22** shows an RF lens **950** transferring power to device **300** in the presence of a multitude of scattering objects **250**. To minimize such effects, the amplitude and phase of the individual radiators of the array may be varied to increase power transfer efficiency. Any one of a number of techniques may be used to vary the amplitude or phase of the individual radiators.

[0108] In accordance with one such technique, to minimize the effect of scattering, a signal is transmitted by one or more of the radiators disposed in the RF lens. The signal(s) radiated from the RF lens is scattered by the scattering objects and received by the radiators (see FIG. **18**). An inverse scattering algorithm is then used to construct the scattering behavior of the environment. Such a construction may be performed periodically to account for any changes that may occur with time. In accordance with another technique, a portion or the entire radiator array may be used to electronically beam-scan the surroundings to construct the scattering behavior from the received waves. In accordance with yet another technique, the device undergoing wireless charging is adapted to periodically send information about the power it receives to the radiator. An optimization algorithm then uses the received information to account for scattering so as to maximize the power transfer efficiency.

[0109] In some embodiments, the amplitude/phase of the radiators or the orientation of the RF lens may be adjusted to take advantage of the scattering media. This enable the scattering objects to have the proper phase, amplitude and polarization in order to be used as secondary sources of radiation directing their power towards the device to increase the power transfer efficiency.

[0110] The above embodiments of the present invention are illustrative and not limitative. Embodiments of the present invention are not limited by number of radiators disposed in an RF lens, nor are they limited by the number of dimensions of an array used in forming the RF lens. Embodiments of the present invention are not limited by the type of radiator, its frequency of operation, and the like. Embodiments of the present invention are not limited by the type of device that may be wirelessly charged. Embodiments of the present invention are not limited by the type of substrate, semiconductor, flexible or otherwise, in which various components of the radiator may be formed. Other additions, subtractions or modifications are obvious in view of the present disclosure and are intended to fall within the scope of the appended claims.

What is claimed is:

1. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a splitter/coupler coupled to the antenna and adapted to split the received RF signal into first and second portions;

a receiver adapted to demodulate the data from the first portion of the RF signal; and

a power recovery unit adapted to convert the second portion of the RF signal to a DC power to power the device.

2. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a receiver adapted to demodulate the data from a first portion of the RF signal;

a power recovery unit adapted to convert a second portion of the RF signal to a DC power to power the device; and

a controller adapted to receive the RF signal from the antenna and generate the first and second portions of the RF signal in accordance with impedance values of the receiver and the power recovery unit.

3. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a switch adapted to receive the RF signal from the antenna;

a power recovery unit adapted to convert the RF signal to a DC power to power the device when the switch is in a first position; and

a receiver adapted to demodulate the data from the received RF signal when the switch is in a second position.

4. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a splitter/coupler coupled to the antenna and adapted to split the received RF signal into first and second portions;

a switch adapted to receive the second portion of the RF signal from the splitter/coupler;

a power recovery unit adapted to convert the second portion of the RF signal to a DC power to power the device when the switch is in a first position; and

a power combiner adapted to receive the first portion of the RF signal from the splitter/coupler and further to receive the second portion of the RF signal when the switch is in a second position; and

a receiver adapted to demodulate the data from an output signal of the power combiner.

5. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a switch coupled to the antenna to receive the RF signal therefrom;

a power combiner coupled to a first output terminal of the switch to receive the RF signal when the switch is in a first position;

a splitter/coupler coupled to a second output terminal of the switch to receive the RF signal when the switch is in a second position, said splitter adapted to split the RF signal into a first portion and a second portion, said splitter/coupler delivering the first portion of the RF signal to the power combiner;

a power recovery unit adapted to convert the second portion of the RF signal to a DC power to charge the device when the switch is in the second position;

a receiver adapted to demodulate the data from an output signal of the power combiner.

6. The device of claim **5** further comprising:

a controller adapted to cause the switch to be in the first position when a power of the received RF signal is less than a threshold value.

7. The device of claim **5** further comprising:

a controller adapted to cause the switch to be in the first position when the device indicates that its DC power exceeds a threshold value.

8. The device of claim **4** further comprising:

a controller adapted to cause the switch to be in the first position when a power of the received RF signal is less than a first threshold value.

9. The device of claim **4** further comprising:

a controller adapted to cause the switch to be in the first position when the device indicates that its DC power exceeds a second threshold value.

10. A method comprising:

receiving an RF signal comprising modulated data;

splitting the received RF signal into first and second portions;

demodulating the data from the first portion of the RF signal; and

converting the second portion of the RF signal to a DC power.

11. A method comprising:

receiving an RF signal comprising modulated data;

demodulating the data from a first portion of the received RF signal via a receiver;

converting a second portion of the RF signal to a DC power via a power recovery unit;

generating the first and second portions of the RF signal in accordance with impedance values of the receiver and the power recovery unit

12. A method comprising:

receiving an RF signal comprising modulated data;

converting the RF signal to a DC power when a switch is in a first position; and

demodulating the data from the received RF signal when the switch is in a second position.

13. A method comprising:

receiving an RF signal comprising modulated data;

demodulating the data using either a first portion of the received RF signal or the received RF signal; and

converting a second portion of the RF signal to a DC power when the first portion of the RF signal is used for demodulating the data.

14. The method of claim **13** further comprising:

demodulating the data using the received RF signal when a power of the received RF signal is less than a first threshold value.

15. The method of claim **14** further comprising:

demodulating the data using the received RF signal when an indication is received that a battery charge exceeds a threshold value.

16. A device comprising:

an antenna adapted to receive an RF signal comprising modulated data;

a controller;

an adjustable splitter/coupler adapted to split the received RF signal into first and second portions in accordance with a value said adjustable splitter/coupler receives from the controller;

a receiver adapted to demodulate the data from the first portion of the RF signal; and

a power recovery unit adapted to convert the second portion of the RF signal to a DC power to power the device.

17. The device of claim **16** wherein said value is defined by a target data rate.

18. The device of claim **16** wherein said value is defined by a DC power requirement of the device.

19. A method comprising:

receiving an RF signal;

splitting the received RF signal into first and second portions in accordance with a received value;

demodulating the data from the first portion of the RF signal; and

converting the second portion of the RF signal to a DC power.

20. The method of claim **19** wherein said value is defined by a target data rate.

21. The device of claim **16** wherein said value is defined by a DC power requirement.

22. The device of claim **1** wherein said splitter/coupler is an adjustable splitter/coupler.

THE SMITHSONIAN INSTITUTION

The Smithsonian Institution is home to more than 141 million objects, ranging in size from insects and diamonds to locomotives and spacecraft. It is the world's largest museum complex, comprising 15 museums and galleries and the National Zoo in Washington DC, and two additional museums in New York City. Millions of visitors each year visit the nation's capital to view such treasures as the Hope Diamond, the Star Spangled Banner, and the Wright Flyer. A broad range of exhibits ensures a fun and educational experience for young and old alike.

One of the world's leading scientific research centers, the Institution has facilities in eight states and the Republic of Panama. Research projects in the arts, history and science are carried out by the Smithsonian all over the world. Some of the Smithsonian's research centers include the Smithsonian Astrophysical Observatory in Cambridge, Massachusetts, the Smithsonian Marine Station at Link Port, in Florida, and the Smithsonian Tropical Research Institute, in Panama.

For membership information of pre-visit planning material, write or call the Visitor Information and Associates Reception Center, Smithsonian Institution, Washington, D. C., 20560, (202) 357-2700 (voice), (202) 357-1729 (TTY). You may also visit the Smithsonian through our web site, www.si.edu.

HISTORY

James Smithson (1765 –1829), a British scientist, drew up his will in 1826 naming his nephew, Henry James Hungerford, as beneficiary. Smithson stipulated that, should the nephew die without heirs (as he did in 1835), the estate would go to the United States to found "at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge..."

On July 1, 1836, Congress accepted the legacy bequeathed to the nation by James Smithson, and pledged the faith of the United States to the charitable trust. In 1838, following approval of the bequest by the British courts, the United States received Smithson's estate—bags of gold sovereigns—then the equivalent of $515,169. Eight years later, on August 10, 1846, an Act of Congress signed by President James K. Polk, established the Smithsonian Institution in its present form and provided for the administration of the trust, independent of the government itself, by a Board of Regents and Secretary of the Smithsonian.

ITEM NO. 3261-08

ADVICE FOR SUPERVISING ADULTS:

- READ AND FOLLOW THESE SAFETY INSTRUCTIONS, THE SAFETY RULES AND KEEP THEM FOR REFERENCE.

- SUPERVISING ADULTS SHOULD DISCUSS ANY WARNINGS AND SAFETY INFORMATION WITH THE CHILD BEFORE COMMENCING THE ACTIVITIES.

SAFETY RULES:

- DO READ THE INSTRUCTIONS BEFORE USE, FOLLOW THEM AND KEEP THEM FOR REFERENCE.
- DO KEEP YOUNG CHILDREN AND ANIMALS AWAY FROM THE ACTIVITY AREA.
- DO STORE THE SET OUT OF REACH OF YOUNG CHILDREN.

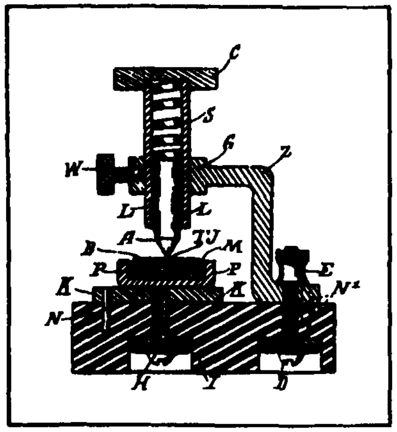
Facts about early crystal development

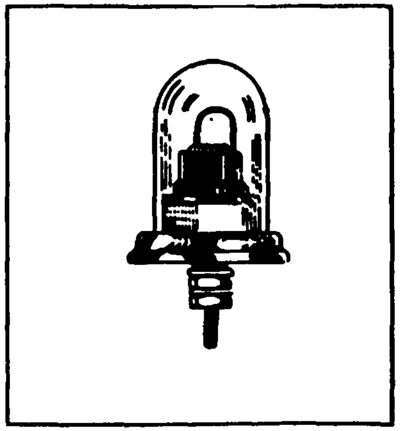
Several inventors receive credit for developing a "crystal detector", a device which can pass current better in one direction than the other in an electrical circuit. In Germany, in the 1870's, Karl F. Braun noticed this property in certain mineral substances. Commercial development required a technology that would be suitable. This came with the advent of wireless communication and radio after 1900.

In Japan, Wichi Torikata investigated many minerals, including zincite, pyrolusite, iron pyrites and galena. In the United States, Greenleaf W. Pickard, associated with the Wireless Specialty Apparatus Co. of Boston, conducted extensive experiments as well. He became well known for the PERIKON Detector which employed zincite and chalcopyrite. The early 20th century work was generally done between 1900 and 1912. Included among the scientists is General H.H.C. Dunwoody of the U.S.Army who developed a carborundum detector.

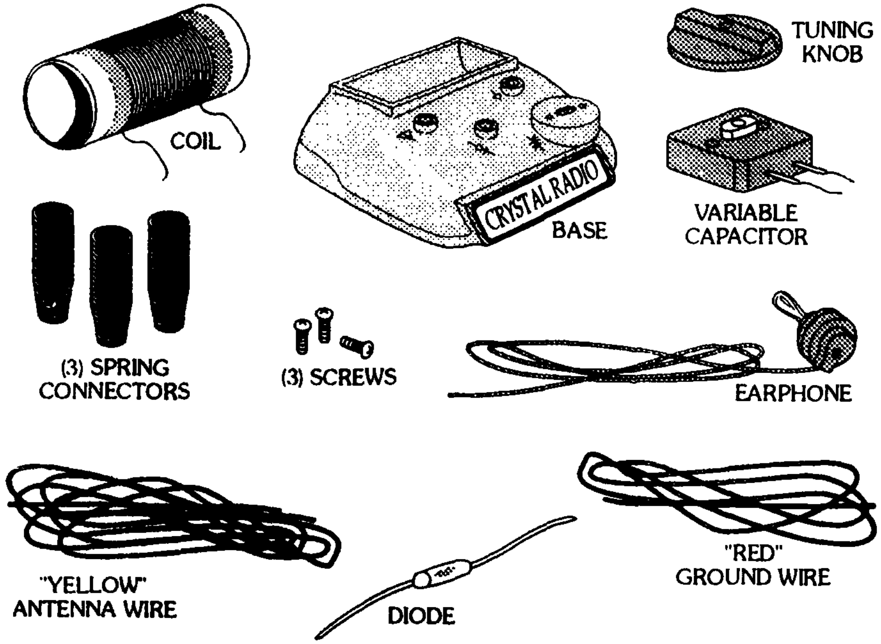
Until radio broadcasting began in 1920 (Station KDKA Pittsburgh) experimenters utilized the crystal detector for radiotelephone communications and for reception of certain Morse Code signals. There was also extensive use by the U.S.Navy and other maritime services.

The modern crystal diode, such as provided with your set, is a spin-off of radar technology developed during World War II. The basic principle, however, remains the same, i.e. to remove the AUDIO (speech, music or Morse-Code) from the radio frequency carrier wave. In one early Pickard crystal design (left) a stiff metal point is adjustable over the crystal surface. In a later version a "Catswhisker" spring impinged on a piece of galena (right) and was varied to give a louder signal.



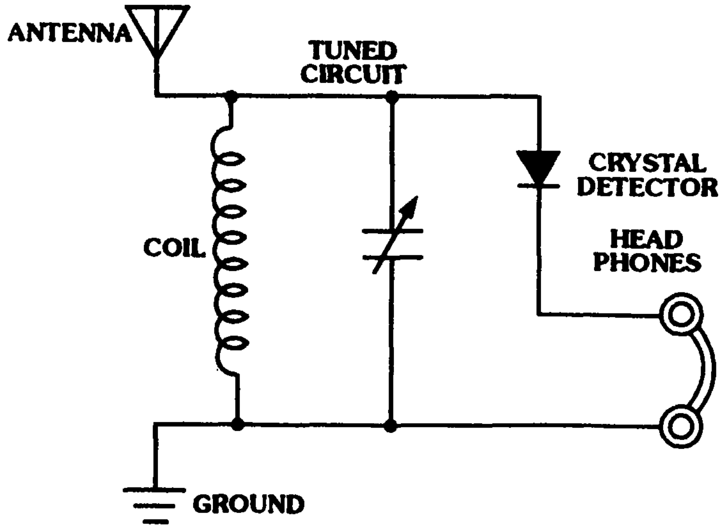


Your Smithsonian Smart Lab Crystal Radio Set contains the following items



COIL
TUNING KNOB
CRYSTAL RADIO
BASE
VARIABLE CAPACITOR
(3) SPRING CONNECTORS
(3) SCREWS
EARPHONE
"YELLOW" ANTENNA WIRE
DIODE
"RED" GROUND WIRE

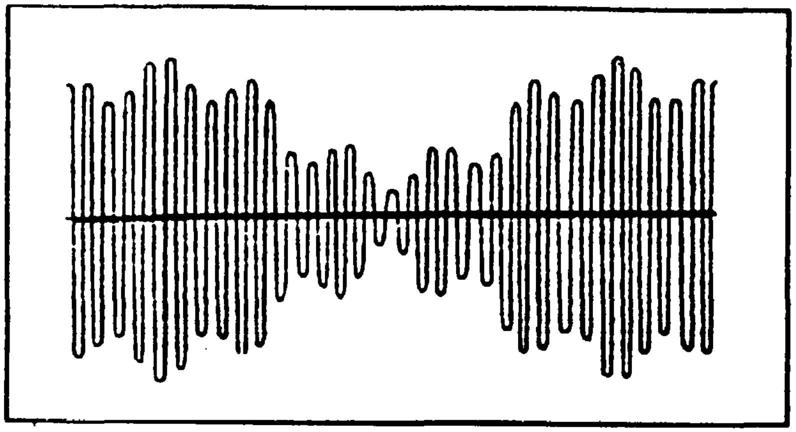
Shown below is a typical wiring diagram of your crystal radio.



ANTENNA
TUNED CIRCUIT
CRYSTAL DETECTOR
HEAD PHONES
COIL
GROUND

Radio Technology (cont'd)

When these two different energy waves are put together by the mixer stage of the transmitter, the resulting wave, which is the signal that the station broadcasts, looks like this:



AM Broadcast Wave

The signal is called a MODULATED wave. You will notice that each of the waves is the same length, but the heights vary. Since the height of a wave is called its AMPLITUDE, The type of transmission that WXYZ uses is called AMPLITUDE MODULATION. That's why WXYZ is called an AM station.

The crystal radio that you built works in just the opposite way as the radio station. The modulated signal broadcast by WXYZ is "picked up" by the antenna on your radio.

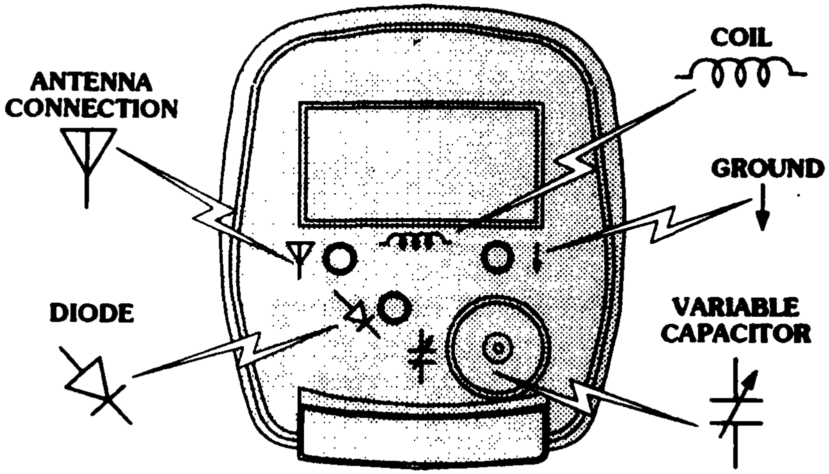
The antenna is connected to the tuner circuit of the radio, which is made up of a coil of wire and a variable capacitor connected together. As you move the tuning knob, you are able to select, or isolate, the particular

This signal is then DEMODULATED by the diode, separating the voice (audio) wave from the carrier wave.

The voice (audio) wave then moves to the earphone, where it is changed back into sound waves that you can hear.

Learn the basic electronic symbols

Before starting to assemble your Smart Lab Crystal Radio please learn the basic electronic symbols that are shown on the plastic base.



Explanation of components

Variable Capacitor - It is used to tune the radio to a station. The leads that are soldered to the lugs are used to connect it to the circuit.

Diode - A small crystal is sealed inside with leads connected to it. Pay careful attention to the position of the black bands painted on the diode close to one end.

Coil- This is a radio-tuning COIL. It was made by winding enameled copper wire around a paper core 80 times. The leads have been stripped and tinned so it can be connected to the circuit.

Earphone - It contains a small crystal that can make enough electricity to drive a metal diaphragm to produce sound. The leads have been stripped and tinned so it can be connected to the circuit.

Antenna - This is a wire used for radiating or receiving radio waves.

Ground - This is a wire used to make a electric connection with the earth or other type of grounding source to create a common return for an electric circuit.

DEAR CUSTOMER:

If we made an error and left something out of this set, or if something is damaged, we are sorry and wish to correct our error.
Please DO NOT return the set to the store where purchased, as the store does not have replacement parts. Instead, write us:

Please include:
1. **Date of Purchase**
2. **Where purchased**
3. **Price paid**
4. **Model Number**
5. **Name of item**
6. **Brief Description of Problem**
7. **Include Sales Slip**

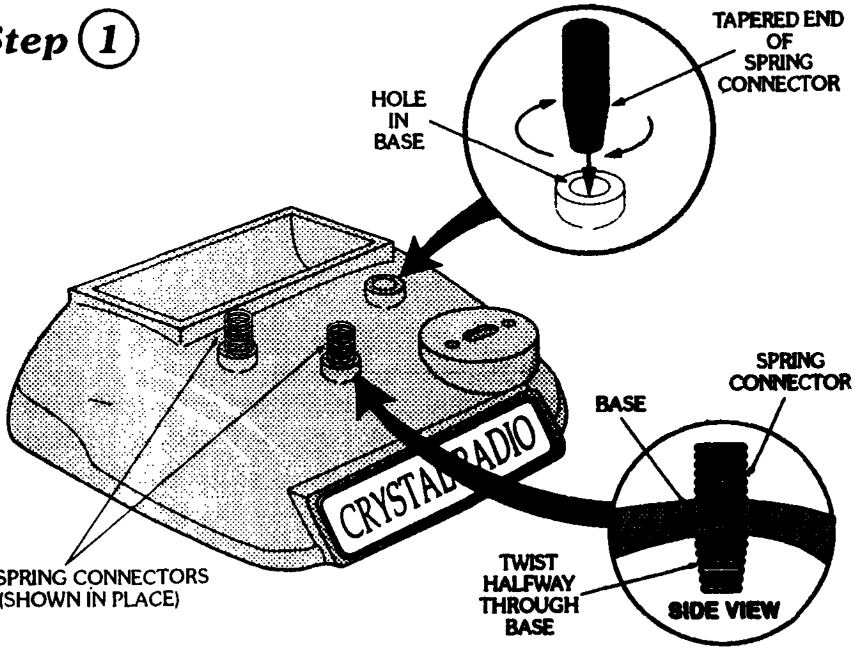
We will do our best to satisfy you. Send your letter to:

NATURAL SCIENCE INDUSTRIES, LTD.
910 ORLANDO AVENUE
WEST HEMPSTEAD, N.Y. 11552-3942
ATTENTION: QUALITY CONTROL DEPT.

How to assemble your Crystal Radio

Before starting, it's important to assemble the parts correctly. Carefully read the following instructions step by step and have fun . . . half the fun is knowing you made your very own crystal radio.

Step ①



TAPERED END OF SPRING CONNECTOR
HOLE IN BASE
SPRING CONNECTOR
BASE
CRYSTAL RADIO
(2) SPRING CONNECTORS (SHOWN IN PLACE)
TWIST HALFWAY THROUGH BASE
SIDE VIEW

A. Locate the three Spring Connectors.
B. Insert one of the Spring Connectors (tapered end first) into one of the three holes on the Base.
C. Push down on the Spring Connector and twist to the right until the Connector is approximately half way through the base.

NOTE: Check to see if the Spring Connecter is inserted halfway through the Base by turning Base upside down (see insert).
D. Insert the remaining two Spring Connectors into the holes on Base the same way.

Radio Technology

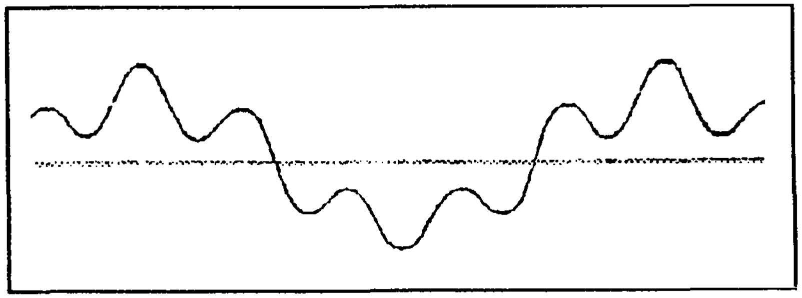
Now that you have your crystal radio assembled and working, it is time to take a brief look at how it works. To do this you are going to take an imaginary trip to a radio station WXYZ, in anytown,USA.

When you arrive at WXYZ, you are met by the station's general manager, Mr. Smith, who is going to show you around.

First, Mr. Smith takes you to a STUDIO, a special room that a program comes from. There is a lot of equipment, including dials and switches, record players, lots and lots of records, and microphones.

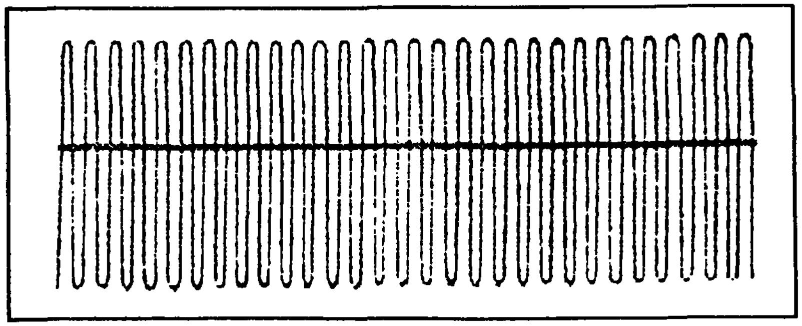
Mr. Smith tells you that when you talk into one of the microphones, your words go into the station's electronic equipment. There, it is mixed with the station's carrier wave, and sent out into the air through the station's transmitting antenna - that tall tower you saw on top of the radio station building.

Then Mr. Smith takes a piece of paper and a pencil, and draws diagrams to show you what happens. He begins by saying that all energy travels in waves, and since the sound we make when we talk is a form of energy, it might look something like this:



Sound Wave

The station's carrier wave is a radio wave, which is also a form of energy, which looks something like this:

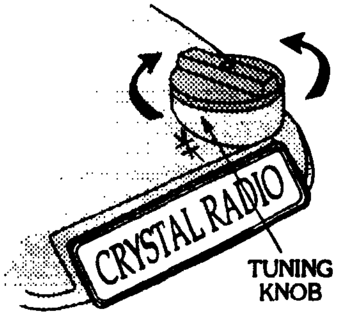


Radio Carrier Wave

How to properly operate your Smart Lab Crystal Radio and troubleshoot

After you have attached all the wires, carefully read the following instructions to make sure your crystal radio operates properly.

A. Place the earphone in your ear and turn the Tuning Knob clockwise and counterclockwise until you pick up the strongest signal.
Note: If you do not pick up a strong signal or do not hear anything, please read some of the troubleshooting solutions explained below.



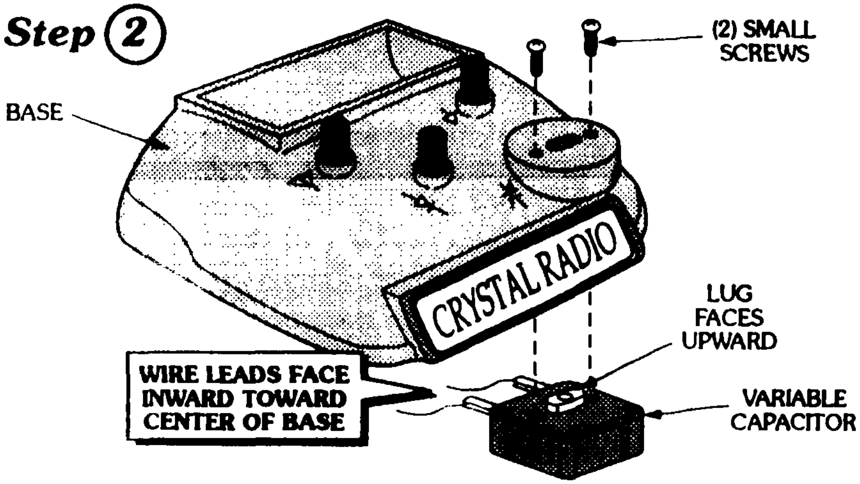
TROUBLESHOOTING HINTS

1. There may be a bad connection caused by improper assembly of your radio. Check all the spring connectors to make sure the wires are attached correctly. If a wire is loose or the bare wire is not making good contact with the spring connector, the radio may not work.
2. If the uninsulated part of the Antenna wire touches anything other than the Antenna Connection on the radio, the radio may work improperly or not at all..
3. If the bare stripped end of the Ground wire is not wrapped tightly around a water pipe (so that it makes good contact), try taping the wire to the shiny part of the pipe using duct tape. If the pipe is dull or rusty, use a piece of sandpaper to gently sand the area where the wire makes contact. Also make sure the wire doesn't touch anything other than the Ground Connection or the radio may not work properly.
4. You may live in an area where radio reception is generally poor. Instead of trying to use your radio during the day, try at night when many radio stations are received better.
5. The Antenna on your radio is a very important component. Make the Antenna as long and high above the ground as possible. If you live in a multi-story dwelling the highest floor should be used when operating the radio. Insulated bell-wire, which is available in hardware stores, makes a very good substitution for your present Antenna.

How to assemble your Crystal Radio (cont'd)

For this step you will need the variable capacitor, (3) screws and turning knob. Be carefull not to misplace the small screws when assembling.

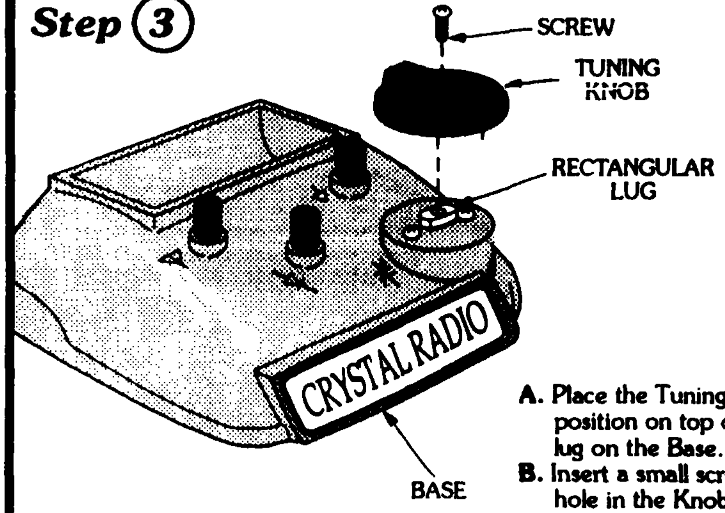
Step ②



A. First place the Variable Capacitor up into the base so the holes on the capacitor line up with the holes on the base.
Note: When you do this be sure the wire leads face inward toward the base as shown and lug faces upward.

B. Next insert the two small screws into the holes on top of the Base and tighten using a small phillips screwdriver.

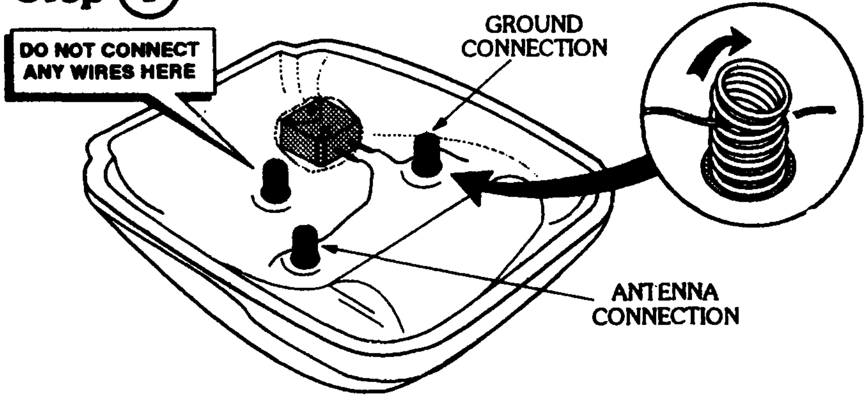
Step ③



A. Place the Tuning Knob into position on top of the rectangular lug on the Base.
B. Insert a small screw into the hole in the Knob and tighten using a phillips screwdriver.

How to assemble your Crystal Radio (cont'd)

Step 4 For this step turn the Base upside down.



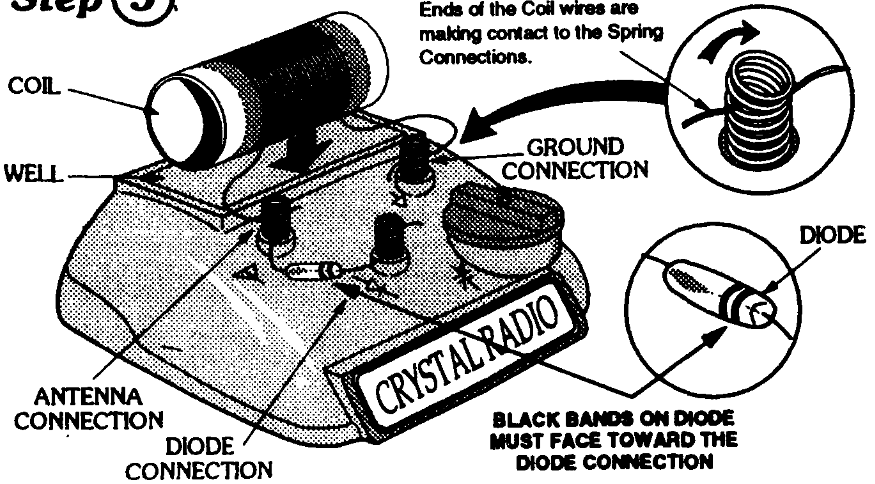
DO NOT CONNECT ANY WIRES HERE
GROUND CONNECTION
ANTENNA CONNECTION

A. Turn the Base upside down.
B. Connect one wire to the Antenna spring connector by bending the spring slightly to one side and inserting the wire through as shown in inset.
C. Connect the other wire to the Ground spring connector in the same manner.

NOTE: Do not connect any of the wires to the Diode spring connector or your crystal set will not work properly.

Step 5

NOTE: Make sure the Plated Ends of the Coil wires are making contact to the Spring Connections.

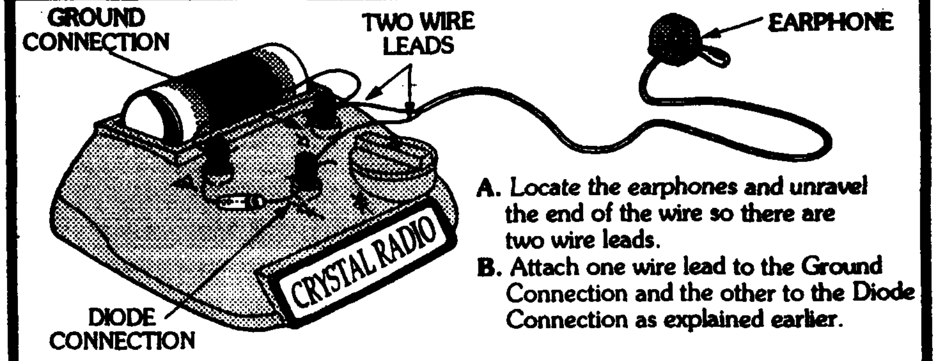


COIL
WELL
GROUND CONNECTION
DIODE
CRYSTAL RADIO
ANTENNA CONNECTION
DIODE CONNECTION

BLACK BANDS ON DIODE MUST FACE TOWARD THE DIODE CONNECTION

A. Next place the Coil in the well of Base with the wires hanging loosely toward the connectors .
B. Connect one of the plated ends of Coil wires to the Ground Connector by bending the Spring Connector as shown in inset. Connect the other Coil wire to the Antenna Connector.
C. Place the Diode between the Diode and Antenna Connections carefully noting the black bands face toward the Diode Connection.
D. Connect ends of Diode wires to Antenna and Diode spring connectors shown.

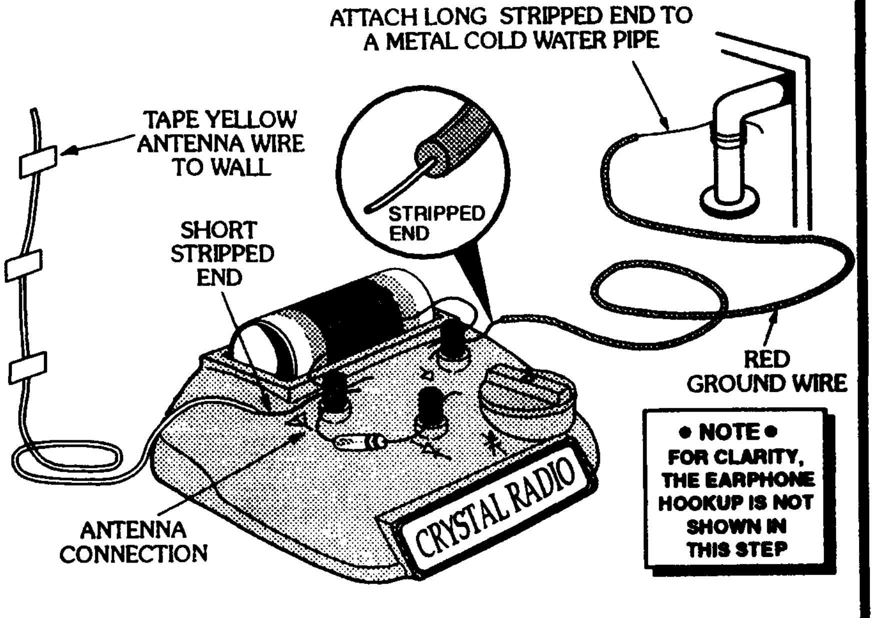
How to attach the earphones



GROUND CONNECTION
TWO WIRE LEADS
EARPHONE
CRYSTAL RADIO
DIODE CONNECTION

A. Locate the earphones and unravel the end of the wire so there are two wire leads.
B. Attach one wire lead to the Ground Connection and the other to the Diode Connection as explained earlier.

Final assembly and operation



ATTACH LONG STRIPPED END TO A METAL COLD WATER PIPE
TAPE YELLOW ANTENNA WIRE TO WALL
STRIPPED END
SHORT STRIPPED END
RED GROUND WIRE
CRYSTAL RADIO
ANTENNA CONNECTION

**• NOTE •
FOR CLARITY, THE EARPHONE HOOKUP IS NOT SHOWN IN THIS STEP**

A. Locate the Red Ground and Yellow Antenna wire.
B. Attach the stripped end of Yellow Antenna wire to the Antenna Connection on the Base.

Note: The Antenna should be strung in a straight line away from power lines and large metal objects. We suggest taping it high up on a wall using masking tape as shown.

C. Next attach the short stripped end of the Ground wire to the Ground Connection.
D. Attach the Long stripped end to a metal cold water pipe, metal radiator pipe, etc., near where the radio will be used. Have a adult help you with this since some pipes may be hot.

Note: If there is not enough stripped, bare wire to wrap around a pipe then ask an adult to strip more insulation off the end using a pair of wire strippers.

Almighty Crystal Radio

A Triple-Ganged Crazy Crystal Radio

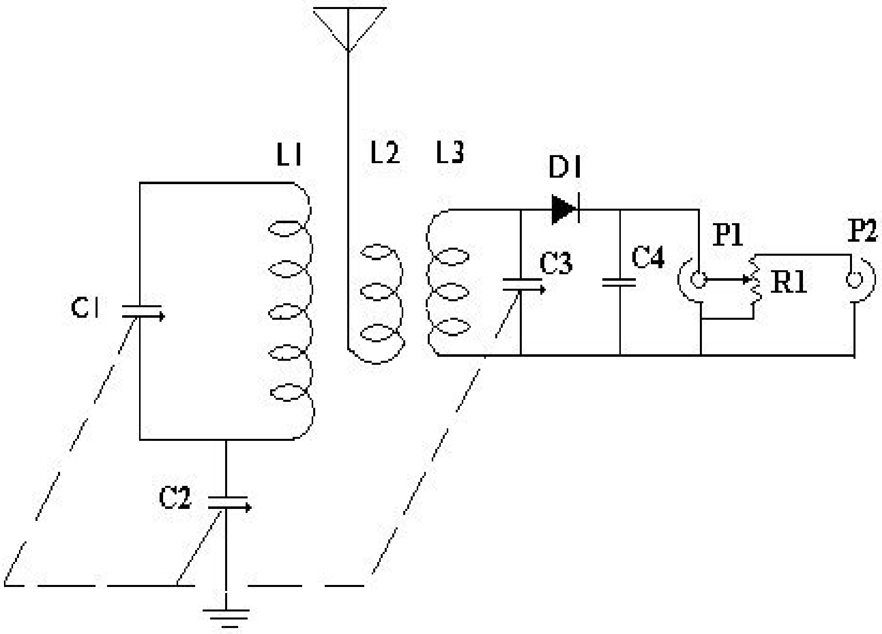
copyright © 2006 by Larry J Solomon

This circuit, of my own design, is my current winner for sensitivity and selectivity. Performance is truly astonshing. When used as a receiver connected to a fine sound system it outperforms several commercial AM radios that I have tested for sound quality.

Pay especial attention to the polarity of the coils when building this set. They are wound clockwise from top to bottom looking down on the coil. All the wire is 24 AWG.

It is also important to use 500pF variables to tune the entire broadcast band. The more common 365pF units will work but will not tune the entire band. Note that the rotor sides of the caps go to ground (green clip in prototype). The stators are the ones with lugs attached (white, red, and yellow alligator clips in prototype picture).

I added a level control to audio output because the output was too loud on most stations using the low level mag input on a receiver, causing distortion. The pot can adjust the level for best fidelity and pulls in almost any local station. An alternative is to use a high level input on the receiver. In that case, omit the pot and P2.



L1 - 50 turns 24 gauge magnet wire

L2 - 15 turns 24 gauge magnet wire wound on top of L1 and L3 separated by a layer of varnish

L3 - 25 turns 24 gauge magnet wire wound parallel to L1 after 12th turn of L1

C1, C2, C3 - 500 pF each, triple ganged air variable capacitors

C4 - 001.uF capacitor

D1 - 1N34 diode or rock crystal

R1 - 400K potentiometer

Coil form 3 inch diameter x 3 inch long

Here is the prototype. The coil was wound with my coil winder, of course.

(57) **ABSTRACT**

An electrical-energy harvesting system envisages a transducer for converting energy from an environmental energy source into a transduced signal, an electrical energy harvesting interface for receiving the transduced signal and for supplying a harvesting signal, and an energy storage element coupled to the electrical energy harvesting interface for receiving the harvesting signal. The electrical-energy harvesting system also includes a voltage converter connected to the electrical energy harvesting interface for generating a regulated voltage. The harvesting interface samples an open-circuit voltage value of the transduced signal, generates an optimized voltage value starting from the open-circuit voltage value, and generates an upper threshold voltage and a lower threshold voltage on the basis of the optimized voltage value. The harvesting interface controls the voltage converter in switching mode so that the harvesting signal has a value between the upper and lower threshold voltages in at least one operating condition.

HIGH-EFFICIENCY ENERGY HARVESTING INTERFACE AND CORRESPONDING ENERGY HARVESTING SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a Continuation of U.S. patent application Ser. No. 14/749,254, filed on Jun. 24, 2015, which is incorporated by reference in its entirety, and which, along with the present application, claims priority to Italian Patent Application TO2014A000735, filed on Sep. 17, 2014.

BACKGROUND

Technical Field

The present disclosure relates to a high-efficiency energy harvesting interface and to a corresponding energy harvesting system.

Description of the Related Art

As is known, systems for harvesting (or scavenging) energy from mechanical or environmental energy sources arouse considerable interest in a wide range of technological fields, for example in the field of portable electronic devices or in the automotive field.

Typically, energy harvesting systems are designed to harvest, store, and transfer energy generated by mechanical or environmental sources to a generic electrical load, which may be supplied, or, in the case of a battery, recharged. These systems thus enable production of electronic apparatuses that operate without a battery, or with a considerable increase in the duration of batteries in the case of apparatuses provided therewith.

For harvesting environmental energy, solar or thermoelectric generators may be used, which convert solar energy and thermal energy, respectively, into electrical energy.

FIG. **1** shows schematically and by functional blocks, an energy harvesting system of a known type.

The energy harvesting system **1** comprises a transducer **2**, for example a photovoltaic or thermoelectric generator that includes a plurality of cells (of a known type, not described in detail herein), which converts solar energy or thermal energy into electrical energy, typically into a DC voltage or, in any case, into a voltage that varies slowly in time (with respect to the electrical constants of the circuit), generating a transduction signal V_{TRANSD}.

The energy harvesting system **1** further comprises a harvesting interface **4**, designed to provide a condition of coupling with the transducer **2** of the MPPT (Maximum Power Point Tracking) type, in order to maximize extraction of power. The harvesting interface **4** is configured to receive at input the transduction signal V_{TRANSD} generated by the transducer **2** and supply at output a harvesting signal VIN_{DCDC}.

The energy harvesting system **1** further comprises: a storage capacitor **5**, which is connected to the output of the harvesting interface **4** and receives the harvesting signal VIN_{DCDC}, which determines charging thereof and consequent storage of energy; and a DC-DC converter **6**, connected to the storage capacitor **5** for receiving at input the stored electrical energy and generating at output a regulated signal V_{REG}, with an appropriate value so that it may be supplied to an electrical load **8**, for its supply or its recharging.

The global efficiency η_{TOT} of the energy harvesting system **1** is given by the expression:

$$\eta_{TOT}=\eta_{TRANSD}\cdot\eta_{MPPT}\cdot\eta_{DCDC}$$

where: η_{TRANSD} is the efficiency of the transducer **2**, indicating the amount of environmental energy, effectively converted by the transducer **2** into electrical energy; η_{MPPT} is the efficiency of the harvesting interface **4**, indicating the amount of converted electrical energy that is effectively used for charging the storage capacitor **5**; and η_{DCDC} is the efficiency of the DC-DC converter **6**.

In particular, the efficiency η_{MPPT} of the harvesting interface **4** indicates the ratio between the power effectively transferred onto the storage capacitor **5** and the maximum power that could theoretically be supplied, P_{MAX}.

In detail, this efficiency η_{MPPT} is given by the following expression:

$$\eta_{MPPT}=\eta_{COUPLE}\cdot\eta_{LOSS}$$

where η_{COUPLE} is the coupling factor between the transducer **2** and the harvesting interface **4** (indicating the impedance matching between the same transducer **2** and the harvesting interface **4**), and η_{LOSS} is the loss of power due to consumption by the harvesting interface **4**.

It has been shown that, in the case of a thermoelectric cell, which may be represented schematically, as illustrated in FIG. **2***a*, as an equivalent voltage generator V_{OC} connected to a series resistance R_{TEG}, the efficiency η_{MPPT} is maximized in the case where the transduction signal V_{TRANSD} has an optimized value V_{MPPT} equal to $V_{OC}/2$ (i.e., a value equal to one half of the load-less, or open-circuit, voltage supplied by the corresponding equivalent voltage generator).

Likewise, in the case of a photovoltaic cell, which may be represented schematically, as illustrated in FIG. **2***b*, as an equivalent current generator I_{PV} connected in parallel to a diode D_{PV} (in the figure, the equivalent series resistance of the generator is not represented), the efficiency η_{MPPT} is maximized in the case where the transduction signal V_{TRANSD} has an optimized value V_{MPPT} comprised between $0.75\cdot V_{OC}$ and $0.9\cdot V_{OC}$ (according to the constructional parameters of the photovoltaic cell and the material of which it is made), for example equal to $0.8\cdot V_{OC}$, where V_{OC} is once again the open-circuit voltage supplied by the photovoltaic cell.

It is consequently required that the harvesting interface **4** of the energy harvesting system **1** be configured in such a way that the transducer **2** operates in, or around, a working point that ensures the aforesaid condition of maximum efficiency.

For this purpose, a wide range of circuit configurations have been proposed for providing the harvesting interface **4**.

For instance, in the document entitled "A Seamless Mode Transfer Maximum Power Point Tracking Controller for Thermoelectric Generator Applications" by Rae-Young Kim, Jih-Sheng Lai, IEEE Transactions on Power Electronics, vol. 23, No. 5, September 2008, an interface circuit has been proposed, comprising a dual voltage conversion stage, formed by the cascade of a boost converter and a buck converter, the latter being designed to regulate the value of the output voltage. Tracking of the MPPT condition is obtained with a continuous-time control of the duty cycle of the boost converter.

The present Applicant has, however, realized that this solution involves a high power consumption, which is due to the fact that the control is of a continuous-time type, which does not render it suited to energy harvesting applications. Further, this solution does not prove flexible, being suited only to a specific type of transducer and to precise values of the electrical parameters associated thereto, further depending upon the tolerance in the values assumed by the same electrical parameters. In general, this solution also involves a large number of external components, which may not be made with integrated technology.

Another possible circuit implementation is described in the document entitled "Thermoelectric Energy Harvesting with 1 mV Low Input Voltage and 390 nA Quiescent Current for 99.6% Maximum Power Point Tracking" by Chao-Jen Huang, Wei-Chung Chen, Chia-Lung Ni, Ke-Horng Chen, Chien-Chun Lu, Yuan-Hua Chu, and Ming-Ching Kuo, 38th European Solid-State Circuits Conference (ESSCIRC), September 2012. This solution envisages a boost converter and a continuous-time algorithm, the so-called perturbation and observation algorithm, to achieve the MPPT condition; in particular, the duty cycle of the converter is perturbed, and the trend of the output voltage is measured: the MPPT condition corresponds to a maximum positive trend.

The present Applicant has, however, realized that also this solution has some disadvantages, amongst which: a high power consumption, intrinsic in a continuous-time perturbation and observation algorithm, which renders it difficult to use in energy harvesting applications; and a poor efficiency, when combined to a low-power transducer.

The document entitled "A Coreless Maximum Power Point Tracking Circuit of Thermoelectric Generators for Battery Charging Systems", by S. Cho, N. Kim, S. Park, S. Kim, IEEE Asian Solid-State Circuits Conference, Nov. 8-10, 2010, Beijing, China, describes yet a further solution for providing the harvesting interface. This solution envisages two conversion stages, with the cascade of a boost conversion stage and a buck conversion stage, the latter for regulation of the output voltage; the MPPT condition is achieved by a control of the switch in the boost stage.

The present Applicant has realized that also this solution, albeit presenting a simpler algorithm to achieve the MPPT condition, does not have a high efficiency, on account of the presence of two conversion stages. Further, also this solution requires a large number of external components, not made with integrated technology.

The subject matter discussed in the Background section is not necessarily prior art and should not be assumed to be prior art merely as a result of its discussion in the Background section. Along these lines, any recognition of problems in the prior art discussed in Background section or associated with such subject matter should not be treated as prior art unless expressly stated to be prior art. Instead, the discussion of any subject matter in the Background section should be treated as part of the inventor's approach to the particular problem, which in and of itself may also be inventive.

BRIEF SUMMARY

The present disclosure provides an energy harvesting interface that will enable the aforementioned problems and disadvantages to be overcome, in full or in part, and in particular that will provide a high efficiency.

According to the present disclosure, an energy harvesting system provided with an energy harvesting interface is consequently provided, as defined in the annexed claims.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

Non-limiting and non-exhaustive embodiments are described with reference to the following drawings, wherein like labels refer to like parts throughout the various views unless otherwise specified. For a better understanding of the present disclosure, preferred embodiments thereof are now

described purely by way of non-limiting example and with reference to the attached drawings, wherein:

FIG. **1** shows an energy harvesting system according to a known embodiment;

FIGS. **2***a* and **2***b* show the equivalent circuit diagrams of a transducer, including a thermoelectric cell or a photovoltaic cell, respectively;

FIG. **3** shows a circuit diagram of an energy harvesting system according to one embodiment of the present solution;

FIG. **4** shows a flowchart relating to operations performed by a harvesting interface in the system of FIG. **3**;

FIGS. **5** and **6***a*-**6***b* show plots of electrical quantities associated with the harvesting interface;

FIG. **7** shows a more detailed circuit diagram of one embodiment of the harvesting interface;

FIGS. **8***a*-**8***d* show plots relating to the electrical performance of the harvesting interface; and

FIG. **9** shows, by way of example, an electronic device, in particular a bracelet or an electronic watch, including the energy harvesting system.

DETAILED DESCRIPTION

As illustrated in FIG. **3**, an energy harvesting system **10** according to one embodiment of the present solution, comprises in general, and substantially as has been described previously: a transducer **12**, in particular a photovoltaic or thermoelectric generator, which generates a transduction signal V_{TRANSD}, in particular a DC voltage or a slowly varying voltage; a harvesting interface **14**, which provides a MPPT coupling, receives the transduction signal V_{TRANSD}, on an input terminal **14***a*, and supplies a harvesting signal VIN_{DCDC}, on an output terminal **14***b*; a storage capacitor **15**, which is connected to the output terminal **14***b* of the harvesting interface **14** and receives the harvesting signal VIN_{DCDC}; and a DC-DC converter **16**, connected to the storage capacitor **15** for receiving the electrical energy stored and generating at output a regulated signal V_{REG}, which is then supplied to an electrical load (here not illustrated), for its supply or recharge.

According to one aspect of the present solution, and as will also be described in detail hereinafter, the harvesting interface **14** comprises: a tracking switch SW_{MPPT}, which is connected between the input terminal **14***a* and the output terminal **14***b* of the harvesting interface **14** and is controlled by a control signal V_{SWMPPT}; a sample-and-hold (S&H) stage **22**, configured to sample the value Voc of the transduction signal V_{TRANSD}, generated by the transducer **12** in an open-circuit or loadless condition, at appropriate time intervals, to generate the optimized value V_{MPPT} (see the foregoing discussion) starting from the value V_{OC}, and to generate an upper threshold voltage VTH_{UP} and a lower threshold voltage VTH_{DOWN}, which satisfy the relation $VTH_{DOWN}<V_{MPPT}<VTH_{UP}$, on the basis of the optimized value V_{MPPT}; a comparator stage **24**, with hysteretic voltage control, on the basis of the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN}, which generates at output an enabling signal EN_{DCDC} for the DC-DC converter **16**; and a timing stage **25**, which generates appropriate control and timing signals for operation of the harvesting interface **14**, amongst which the aforesaid control signal V_{SWMPPT}.

In general, operation of the harvesting interface **14** envisages, upon opening of the tracking switch SW_{MPPT}, sampling of the value of the transduction signal V_{TRANSD}, with the transducer **12** operating in loadless conditions, and corresponding generation of the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN}; and subsequently, upon closing of the tracking switch SW_{MPPT}, generation of the harvesting signal VIN_{DCDC}, with a value comprised between the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN} (thanks to the hysteretic control by the comparator stage **24**), and thus about the optimized value V_{MPPT}. Given that, for closing of the tracking switch SW_{MPPT}, the value of the harvesting signal VIN_{DCDC} coincides with the value of the transduction signal V_{TRANSD}, the condition of energy transfer into the storage capacitor **15** thus occurs in an MPPT condition, with substantially maximum efficiency and substantially maximum coupling between the transducer **12** and the harvesting interface **14**.

Conveniently, the S&H stage **22** is controlled by the timing stage **25** for sampling and periodically refreshing the value V_{OC} and consequently the values of the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN} in such a way as to react promptly and adapt to possible variations of the operating conditions of the transducer **12**.

In detail, the S&H stage **22** of the harvesting interface **14** comprises: a sampling switch $SW_{S\&H}$, which is connected between the input terminal **14***a* of the harvesting interface **14** and a first internal node **N1** and receives a control signal $V_{SWS\&H}$; a voltage divider **30**, formed by a first dividing resistor $R1_{S\&H}$, connected between the first internal node **N1** and a second internal node **N2**, and a second dividing resistor $R2_{S\&H}$, connected between the second internal node **N2** and a reference terminal, or ground, GND (both dividing resistors $R1_{S\&H}$, $R2_{S\&H}$ have a resistance value much higher than the value of the series resistance of the equivalent generator of the transducer **12**); a first decoupling switch **SW1**, which is connected between the second internal node **N2** and a third internal node **N3** and receives a control signal V_{SW1}; a first holding capacitor $C1_{S\&H}$, connected between the third internal node **N3** and the reference terminal GND; a first voltage-generator module **32**, which is connected between the third internal node **N3** and a fourth internal node **N4** and is designed to generate an offset voltage V_{OS}; a second voltage-generator module **34**, which is connected between the third internal node **N3** and a fifth internal node **N5** and is designed to generate the same offset voltage V_{OS}; a second holding capacitor $C2_{S\&H}$, connected between the fourth internal node **N4** and the reference terminal GND; and a third holding capacitor $C3_{S\&H}$, connected between the fifth internal node **N5** and the reference terminal GND.

The comparator stage **24** comprises: a comparator **35**, including in a per se known manner an appropriately configured operational amplifier, having a first input terminal connected to the output terminal **14***b* of the harvesting interface **14**, a second input terminal, and an output terminal, which is connected to an enabling input of the DC-DC converter **16** and is designed to supply the enabling signal EN_{DCDC}; a first comparison switch $SW1_{COMP}$, which is connected between the fourth internal node **N4** of the harvesting interface **14** and the second input terminal of the comparator **35** and receives a control signal $V_{SW1COMP}$; and a second comparison switch $SW2_{COMP}$, which is connected between the fifth internal node **N5** of the harvesting interface **14** and the second input terminal of the comparator **35**, and receives, as a control signal, the enabling signal EN_{DCDC}.

The timing stage **25**, including in a per se known manner (not described in detail herein), an oscillator circuit, is configured to generate the control signals V_{SWMPPT}, $V_{SWMS\&H}$, V_{SW1}, $V_{SW1COMP}$ for the switches SW_{MPPT}, $SW_{MS\&H}$, **SW1**, $SW1_{COMP}$, according to a timing algorithm described in detail hereinafter. As will be discussed hereinafter, the timing stage **25** may supply further control signals for further switches that may be present in the circuit.

With reference also to the flowchart of FIG. **4**, operation of the harvesting interface **14** envisages that in an initial step **40** the value of the loadless or open-circuit voltage V_{OC} of the transduction signal V_{TRANSD} supplied by the transducer **12** is sampled and held.

For this purpose, the tracking switch SW_{MPPT} is driven into the opening condition, and the sampling switch $SW_{S\&H}$ is driven into the closing condition; in this step, the DC-DC converter **16** is turned off, and the first decoupling switch **SW1** is further driven into the closing condition.

The transducer **12** operates substantially in an open-circuit condition, given that the resistance as a whole supplied by the voltage divider **30** is much higher than its own equivalent series resistance, so that the value of the transduction signal V_{TRANSD} that is supplied and that is present on the first internal node **N1** substantially coincides with the loadless or open-circuit voltage V_{OC}.

In this situation, the voltage divider **30**, by an appropriate choice of the division ratio, generates on the second internal node **N2** a sampled voltage $V_{S\&H}$ having a value substantially equal to $V_{OC}/2$, in the case where the transducer **12** implements a thermoelectric cell, or comprised between $0.75\cdot V_{OC}$ and $0.9\cdot V_{OC}$, for example substantially equal to $0.8\cdot V_{OC}$, in the case where the transducer **12** implements, instead, a photovoltaic cell.

In any case, the value of the sampled voltage $V_{S\&H}$ corresponds to the value that the transduction signal V_{TRANSD} supplied by the transducer **12** assumes in a maximum efficiency or maximum coupling operating condition, i.e., to the optimized value V_{MPPT}, thus depending upon the electrical and constructional characteristics of the same transducer **12**.

The first holding capacitor $C1_{S\&H}$ is consequently charged to the aforesaid optimized value V_{MPPT} assumed by the sampled voltage $V_{S\&H}$.

In detail, the sampled voltage $V_{S\&H}$ is given by the following expression:

$$V_{S\&H}=V_{OC}\cdot R2_{S\&H}/(R1_{S\&H}+R2_{S\&H})$$

Consequently, the values of resistance of the dividing resistors $R1_{S\&H}$, $R2_{S\&H}$ are set, or regulated, in such a way that:

$$R2_{S\&H}=R1_{S\&H};\ R2_{S\&H}/(R1_{S\&H}+R2_{S\&H})=\tfrac{1}{2}$$

in the case where the transducer **12** implements a thermoelectric cell, and for example:

$$R2_{S\&H}=4\cdot R1_{S\&H};\ R2_{S\&H}/(R1_{S\&H}+R2_{S\&H})=0.8$$

in the case where the transducer **12** implements a photovoltaic cell, having a maximum efficiency in the condition $V_{MPPT}=0.8\cdot V_{OC}$.

It is noted that it is thus advantageous to provide at least one, or both, of the dividing resistors $R1_{S\&H}$, $R2_{S\&H}$ so that their resistance is configurable for generating the optimal value for the voltage V_{MPPT}.

Next (step **42**), once again with the tracking switch SW_{MPPT} open and the DC-DC converter **16** turned off, the values of the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN}, at which the second and third holding capacitors $C2_{S\&H}$, $C3_{S\&H}$, respectively, are charged, are generated

$$VTH_{UP}=V_{S\&H}+V_{OS};\text{ and}$$

$$VTH_{DOWN}=V_{S\&H}-V_{OS}.$$

Then (step **44**), the sampling switch $SW_{S\&H}$ is driven into the opening condition, as likewise the first decoupling switch **SW1**. In this way, the voltage values stored in the holding capacitors $C2_{S\&H}$, $C3_{S\&H}$ are held, but for the leakage currents, which are in any case minimized with an appropriate design of the switching elements in the circuit.

Furthermore, the tracking switch SW_{MPPT} is driven into the closing condition, thus starting the step of tracking of the value of the transduction signal V_{TRANSD}, which enables substantially maximum efficiency and substantially maximum coupling to be obtained. The first comparison switch $SW1_{COMP}$ is further driven into the closing condition so that the second input terminal of the comparator **35** is at the upper threshold voltage VTH_{UP}.

As mentioned previously, the tracking step envisages that the DC-DC converter **16** is turned on/turned off via the hysteretic control of the comparator **24**, which generates the enabling signal EN_{DCDC}, causing the harvesting signal VIN_{DCDC} (and consequently the transduction signal V_{TRANSD}, given the presence of the short circuit defined by the tracking switch SW_{MPPT} in a closing condition) to have a variable trend between the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN}, thus around the sampled voltage $V_{S\&H}$, i.e., the optimized value V_{MPPT}.

In detail, the DC-DC converter **16** stays off as long as the value of the harvesting signal VIN_{DCDC} is lower than the upper threshold voltage VTH_{UP}, as verified in step **45**.

As soon as the value of the harvesting signal VIN_{DCDC} exceeds the upper threshold voltage VTH_{UP}, step **46** (subsequent to step **45**), the enabling signal EN_{DCDC} switches (going, for example, to the high state), enabling the DC-DC converter **16**, which is consequently turned on.

It should be noted that switching of the same enabling signal EN_{DCDC} further controls closing of the second comparison switch $SW2_{COMP}$, so that the second input terminal of the comparator **35** goes to the lower threshold voltage VTH_{DOWN}, thus guaranteeing hysteretic operation of the comparator **25**.

Furthermore, activation of the DC-DC converter **16** entails a decrease in the value of the harvesting signal VIN_{DCDC}, since the average current in the DC-DC converter **16** (when it is on) is higher than the current supplied by the transducer **12**. In this step, the capacitance of the storage capacitor **15** is thus discharged with substantially constant current (when, instead, the DC-DC converter **16** is off, the same capacitance is charged by the transducer **12**).

In the same step **46**, count of a refresh time interval is started, following upon which, as described in detail hereinafter, the values of the sampled voltage $V_{S\&H}$ and of the threshold voltages VTH_{UP}, VTH_{DOWN} will have to be updated.

The DC-DC converter **16** remains on as long as the value of the harvesting signal VIN_{DCDC} is higher than the lower threshold voltage VTH_{DOWN}, as verified in step **47**.

As soon as the value of the harvesting signal VIN_{DCDC} drops below the lower threshold voltage VTH_{DOWN}, the enabling signal EN_{DCDC} switches again (going, for example, to the low state), disabling the DC-DC converter **16**, which is consequently turned off (step **48**).

Switching of the same enabling signal EN_{DCDC} further controls opening of the second comparison switch $SW2_{COMP}$ so that the second input terminal of the comparator **35** once again goes to the upper threshold voltage VTH_{UP}.

Furthermore, deactivation of the DC-DC converter **16**, entails an increase in the voltage of the harvesting signal VIN_{DCDC} on account of the current drawn by the transducer **12**.

The aforesaid steps of increase and decrease of the value of the harvesting signal VIN_{DCDC} (and consequently of the transduction signal V_{TRANSD}) repeats one after the other until the refresh time interval reaches a desired value (this value may conveniently be regulated, also during operation of the circuit), as verified in the same step **48**.

In this case, from step **48**, control returns to the initial step **40**, for a new sampling of the open-circuit voltage V_{OC} supplied by the transducer **12**, and refresh of the sampled voltage values and of the threshold values, in a manner altogether similar to what has been described previously.

The operation described will be better understood with reference also to the diagrams of FIG. **5**, which show the plots of the harvesting signal VIN_{DCDC} and of the transduction signal V_{TRANSD}, during the steps of tracking of the MPPT condition, with duration T_{MPPT}, and of refresh and sampling, with duration T_{SAMPLE}; further indicated are the time intervals in which the DC-DC converter **16** is on and those in which the DC-DC converter **16** is off, in each on/off cycle, having a duration T_{CYCLE}.

In particular, the time interval T_{MPPT} is much longer than the time interval T_{SAMPLE}: $T_{MPPT} >> T_{SAMPLE}$.

In general, time interval T_{MPPT} depends on the field of application, in particular on the fact that the environmental conditions to which the transducer **12** is subjected change rapidly; for example, the time interval T_{SAMPLE} may be of the order of some tens of milliseconds (for example, 25 ms) and the time interval T_{MPPT} may range from some seconds to some tens of seconds.

The above characteristic advantageously enables a considerable reduction of the average current consumption. During the tracking step, in effect, only the comparator **25** is on, with a resulting extremely low current consumption.

Purely by way of example, in the aforesaid FIG. **5**, the open-circuit voltage V_{OC} supplied by the transducer **12** increases with each refresh of the values sampled. It is, however, altogether evident that, upon start of the refresh time interval, the value of the transduction signal V_{TRANSD} may vary arbitrarily (for example, as a function of the changed environmental conditions, in terms of temperature or conditions of lighting), thus being able to increase, or even decrease, with respect to the immediately preceding step, according to the environmental stimulus.

As illustrated in FIGS. **6***a*, **6***b*, corresponding to an increase of the open-circuit voltage V_{OC} supplied by the transducer **12** is a decrease in the time interval T_{CYCLE}, defined previously; thus, a larger number of cycles during the step of tracking of the MPPT condition occur.

By way of example, FIG. **6***a* refers to a voltage V_{OC} of 0.4 V, whereas FIG. **6***b* refers to a voltage V_{OC} of 5 V.

FIG. **7** shows a possible circuit implementation for providing the first and second voltage-generator modules **32**, **34**, which enables substantially negligible leakage currents to be obtained.

In particular, the harvesting interface **14** (of which elements already described previously with reference to FIG. **3** are not described again) comprises in this case a voltage-tracking amplifier **50**, having its input connected to the third internal node N_3 and its output defining a sixth internal node N_6, onto which the sampled voltage $V_{S\&H}$ is thus brought.

Connected between the sixth internal node N_6 and the reference terminal GND is a first mirroring resistor **51** with resistance R_S, through which a mirroring current I_S, equal to $V_{S\&H}/R_S$, is consequently generated.

The harvesting interface **14** further comprises a current mirror **52** (obtained in a per se known manner, not described in detail herein), having a mirroring branch connected to the sixth internal node N_6 and a mirrored branch connected to a seventh internal node N_7, on which the mirroring current I_S is mirrored.

Connected between the seventh internal node N_7 and the reference terminal GND is a second mirroring resistor **54** with the same resistance R_S, so that on the seventh internal node N_7 there is the same sampled voltage $V_{S\&H}$.

The first voltage-generator module **32** is formed in this case by: a first current generator **55**, which may be selectively connected to the seventh internal node N_7 by a second decoupling switch SW**2** and generates a reference current I_{ref}; and a third decoupling switch SW**3**, designed to connect the seventh internal node N_7 selectively to the fourth internal node N_4, on which the upper threshold voltage VTH_{UP} is present during operation. The first current generator **55** may be obtained in any known way.

The second voltage-generator module **34** is in turn formed by: a second current generator **57**, which may be selectively connected to the same seventh internal node N_7, as an alternative to the first current generator **55**, via a fourth decoupling switch SW**4**, and generates the same reference current I_{ref}; and a fifth decoupling switch SW**5**, designed to connect the seventh internal node N_7 selectively to the fifth internal node N_5, on which the lower threshold voltage VTH_{DOWN} is present during operation. Also the second current generator **55** may be obtained in any known way.

The second, third, fourth, and fifth decoupling switches receive respective control signals from the same timing stage **25** (in a way not illustrated here, and as it has been discussed previously).

Operation of the circuit described envisages, as mentioned previously, in an initial step, sampling of the open-circuit voltage of the transducer **12** by closing of the sampling switch $SW_{S\&H}$ and of the first decoupling switch SW**1**, and consequent generation on the third internal node N**3** of the sampled voltage $V_{S\&H}$, having a value corresponding to the optimized value V_{MPPT}.

Next, the sampling switch $SW_{S\&H}$ and the first decoupling switch SW**1** are both opened, and the sampled voltage $V_{S\&H}$ is held on the first holding capacitor $C\mathbf{1}_{S\&H}$.

Next, but once again within the sampling time interval T_{SAMPLE}, the second and third decoupling switches SW**2**, SW**3** are first closed (with the fourth and fifth decoupling switches SW**4**, SW**5** open) so that on the seventh internal node N**7**, and consequently on the fourth internal node N**4**, the voltage $VTH_{UP}=V_{S\&H}+I_{REF}\cdot R_S$ is generated (note that the aforesaid offset voltage V_{OS} consequently corresponds here to $I_{REF}\cdot R_S$).

Next, once again within the sampling time interval T_{SAMPLE}, the second and third decoupling switches SW**2**, SW**3** are opened, and the fourth and fifth decoupling switches SW**4**, SW**5** are closed so that the voltage $VTH_{DOWN}=V_{S\&H}-I_{REF}\cdot R_S$ is generated on the seventh internal node N**7**, and consequently on the fifth internal node N**5**.

Next, also the fourth and fifth decoupling switches SW**4**, SW**5** are opened so that the upper and lower threshold voltages VTH_{UP}, VTH_{DOWN} are held on the respective second and third holding capacitors $C\mathbf{2}_{S\&H}$, $C\mathbf{3}_{S\&H}$ (for the entire duration of the subsequent tracking time interval T_{MPPT}), with minimal leakage currents through the open switches.

In this regard, the present Applicant has realized: a substantially maximum dispersion by the holding capacitors $C\mathbf{2}_{S\&H}$, $C\mathbf{3}_{S\&H}$ equal to 10 mV/s with an open-circuit voltage V_{OC} of 0.4 V (that is, equal to 5% of the optimal voltage V_{MPPT}, in the example 0.2 V, considering a duration of the time interval T_{MPPT} of one second); and a substantially maximum dispersion by the same holding capacitors $C\mathbf{2}_{S\&H}$, $C\mathbf{3}_{S\&H}$ equal to 100 mV/s with an open-circuit voltage V_{OC} of 5V (equal approximately to 2% of the optimal voltage V_{MPPT}, in the example 2.5V, considering once again a duration of the time interval T_{MPPT} of one second).

The performance achieved by the harvesting interface **14** is further highlighted by the plots of FIGS. **8***a*-**8***d*, which refer to use with a transducer **12** of a thermoelectric type, having the following characteristics: series resistance R_{TEG} of 20 kΩ, open-circuit voltage V_{OC} comprised between 1 V (minimum value) and 5 V (maximum value).

In detail, FIG. **8***a* shows the average consumption of the S&H stage **22** as the average power delivered by the transducer **12** (available power P_{MAX}) varies. It should be noted that this consumption is very contained and barely dependent upon the average power delivered, and thus barely dependent upon the environmental conditions in which the transducer **12** operates and upon the electrical characteristics of the same transducer **12**.

FIG. **8***b* shows the plot of the factor η_{LOSS} (see the foregoing discussion) as a function of the same power P_{MAX}.

FIG. **8***c* shows the plot of the factor η_{COUPLE} (see the foregoing discussion), once again as a function of the power P_{MAX}.

FIG. **8***d* shows the plot of the efficiency η_{MPPT} (see the foregoing discussion) once again as a function of the power P_{MAX}.

In particular, it is to be noted that the efficiency η_{MPPT} is higher than 90% with an available power of 20 μW, and rises above 98% with an available power higher than 100 μW.

The advantages of the proposed solution emerge clearly from the foregoing description.

In particular, the hysteretic voltage control for tracking of the MPPT condition enables a considerable saving in power consumption, for example as compared to a continuous-time control solution.

For instance, the condition $T_{MPPT}>>T_{SAMPLE}$ enables considerable accuracy in tracking of the aforesaid MPPT condition and a very high value of the factor η_{COUPLE} to be achieved.

Furthermore, the harvesting interface **14** does not envisage the use of further DC/DC converters to ensure the MPPT condition, thus reducing the number of external components required; a voltage control is in fact implemented, instead of a duty-cycle control, as in many known solutions.

In this regard, it is further pointed out that in the solution described, the holding capacitors are advantageously all obtained using integrated technology, not as external components (in fact, thanks to the reduction of the leakage currents, the value of the same capacitors may not be high).

The solution described further proves very flexible, enabling easy adaptation to use with different photovoltaic or thermoelectric cells; in particular, it is sufficient to regulate the division factor of the sampled voltage $V_{S\&H}$ via the voltage divider **30** to obtain a condition of improved matching.

Furthermore, once the operating mode has been selected, with a thermoelectric cell or a photovoltaic cell, the efficiency of tracking of the MPPT condition is found to be independent of the electrical parameters of the transducer **12**, for example of the corresponding equivalent resistance or the corresponding open-circuit voltage.

As mentioned previously, the energy harvesting system may advantageously be used for electrical supply of a device, which may even be without any battery, or equipped with a rechargeable battery.

By way of example, FIG. **9** shows an electronic bracelet or watch **60**, which incorporates the energy harvesting system for generation of electrical energy by exploiting the difference of temperature between the environment and the human body (the transducer **12** is in this case of a thermoelectric type). The electronic bracelet **60** may advantageously be used in the field of fitness, for example for counting the steps made by a user.

Finally, it is clear that modifications and variations may be made to what has been described and illustrated herein, without thereby departing from the scope of the present disclosure, as defined in the annexed claims.

In particular, the energy harvesting system **10** may comprise a plurality of transducers **12**, all of the same type or of a type different from one another.

Furthermore, it is evident that the energy harvesting system **10** may advantageously be used for other applications and other electronic devices, for example in the automotive field, or also in a mobile electronic device or in a garment or other article of clothing, for example in footwear, in the consumer electronics field (any mobile application), the industrial field (for example, in controlling processes that involve environments with high thermal gradients), or in the field of home automation (for example, in combination with photovoltaic generators).

The various embodiments described above can be combined to provide further embodiments. These and other changes can be made to the embodiments in light of the above-detailed description. In general, in the following claims, the terms used should not be construed to limit the claims to the specific embodiments disclosed in the specification and the claims, but should be construed to include all possible embodiments along with the full scope of equivalents to which such claims are entitled. Accordingly, the claims are not limited by the disclosure.

The invention claimed is:

1. An electrical-energy harvesting system, comprising:

a transducer to convert energy from an environmental energy source into a transduced signal;

a harvesting interface to receive the transduced signal on an input terminal and to supply an electrical-energy harvesting signal on an output terminal;

an energy storage element coupled to the output terminal of the harvesting interface to receive the electrical-energy harvesting signal;

a voltage converter coupled to the output terminal to generate a regulated voltage, wherein the harvesting interface is configured to:

sample an open-circuit voltage value of the transduced signal;

couple the output terminal to the input terminal during a tracking operating condition;

generate an optimized voltage value starting from the open-circuit voltage value;

decouple the output terminal from the input terminal during a refresh operating condition of sampling said open-circuit voltage value;

generate an upper threshold voltage based on the optimized voltage value during said refresh operating condition;

generate a lower threshold voltage based on the optimized voltage value during said refresh operating condition; and

control the voltage converter in a switching mode to thereby maintain the electrical-energy harvesting signal between the upper and lower threshold voltages in said tracking operating condition.

2. The system according to claim **1**, wherein the tracking operating condition is a condition of maximum power-point tracking.

3. The system according to claim **2**, wherein the harvesting interface further comprises:

a timing stage to generate control and timing signals to first determine said tracking operating condition and then to determine said refresh operating condition.

4. The system according to claim **3**, wherein said timing stage is configured to:

cyclically determine execution of said refresh operating condition to direct updating said open-circuit voltage value and said upper and lower threshold voltages and execution of said tracking operating condition following upon each new execution of said refresh operating condition.

5. The system according to claim **1**, wherein said optimized voltage value corresponds to a condition of substantially maximum coupling between said transducer and said harvesting interface.

6. The system according to claim **1**, wherein:

$$VTH_{DOWN}<V_{MPPT}<VTH_{UP},$$

where V_{MPPT} is the optimized voltage value, VTH_{DOWN} is the lower threshold voltage, and VTH_{UP} is the upper threshold voltage.

7. The system according to claim **1**, wherein the harvesting interface comprises

a voltage divider to generate the optimized voltage value starting from a sampled value of said open-circuit voltage, said optimized voltage being substantially equal to 50 percent of the sampled value of said open circuit voltage supplied by the transducer.

8. The system according to claim **1**, wherein the harvesting interface comprises:

a voltage divider to generate the optimized voltage value starting from a sampled value of said open-circuit voltage, said optimized voltage being between about 75 percent and about 90 percent of the sampled value of said open circuit voltage supplied by the transducer.

9. An electronic device, comprising:

a transducer to convert energy from an environmental or mechanical energy source into a transduced signal;

a harvesting interface to receive the transduced signal on an input terminal and to supply an electrical-energy harvesting signal on an output terminal;

an energy storage element coupled to the output terminal of the harvesting interface to receive the electrical-energy harvesting signal;

a voltage converter coupled to the output terminal to generate a regulated voltage, wherein the harvesting interface is configured to:

sample an open-circuit voltage value of the transduced signal;

couple the output terminal to the input terminal during a tracking operating condition;

control the voltage converter in a switching mode to thereby maintain the electrical-energy harvesting signal between an upper threshold voltage and a lower threshold voltages in said tracking operating condition;

decouple the output terminal from the input terminal during a refresh operating condition of sampling said open-circuit voltage value;

generate said upper and lower threshold voltages during said refresh operating condition; and

cyclically execute said tracking operating condition following upon each new execution of said refresh operating condition; and

an electrical load to receive the regulated voltage.

10. The electronic device according to claim **9**, wherein said electrical load includes a rechargeable battery.

11. The electronic device according to claim **9**, wherein said transducer includes at least one of a photovoltaic and a thermoelectric device.

12. The electronic device according to claim **9**, wherein said electronic device is a mobile electronic device, an automotive device, an industrial device, an article of clothing, or a fitness device.

13. The electronic device according to claim **9**, wherein said tracking operating condition is a condition of maximum power-point tracking.

14. The electronic device according to claim **9**, wherein:

$$VTH_{DOWN}<V_{MPPT}<VTH_{UP},$$

where V_{MPPT} is the optimized voltage value, VTH_{DOWN} is a lower threshold voltage, and VTH_{UP} is an upper threshold voltage.

15. An electrical-energy harvesting method, comprising:

by a transducer, converting energy from an environmental energy source into a transduced signal;

by a harvesting interface:

receiving the transduced signal on an input terminal;

supplying an electrical-energy harvesting signal on an output terminal;

sampling an open-circuit voltage value of the transduced signal;

coupling the output terminal to the input terminal during a tracking operating condition;

generating an optimized voltage value starting from the open-circuit voltage value;

decoupling the output terminal from the input terminal during a refresh operating condition of sampling said open-circuit voltage value;

generating an upper threshold voltage based on the optimized voltage value during said refresh operating condition;

generating a lower threshold voltage based on the optimized voltage value during said refresh operating condition; and

controlling a voltage converter in a switching mode to maintain the electrical-energy harvesting signal between the upper and lower threshold voltages in said tracking operating condition;

by an energy storage element coupled to the output terminal of the harvesting interface, receiving the electrical-energy harvesting signal and storing electrical energy; and

by the voltage converter coupled to the output terminal, generating a regulated voltage.

16. The method according to claim **15**, wherein said tracking operating condition is a condition of maximum power-point tracking.

17. The method according to claim **16**, further comprising, by a timing stage of the harvesting interface:

generating control and timing signals to first determine said tracking operating condition and then to determine said refresh operating condition.

18. The method according to claim **17**, further comprising, by the timing stage:

cyclically determining execution of said refresh operating condition;

updating said open-circuit voltage value and said upper and lower threshold voltages; and

executing said tracking operating condition following upon each new execution of said refresh operating condition.

19. The method according to claim **15**, wherein said transducer includes at least one of a photovoltaic and a thermoelectric device.

20. The method according to claim **15**, wherein said transducer is integrated in a mobile electronic device, an automotive device, an industrial device, an article of clothing, or a fitness device.

(57) **ABSTRACT**

An energy harvesting interface receives an electrical signal from an inductive transducer and supplies a supply signal. The interface includes an input branch with a first switch and a second switch connected together in series between a first input terminal and an output terminal. The interface further includes a third switch and a fourth switch connected together in series between a second input terminal and the output terminal. A first electrical-signal-detecting device, coupled across the second switch, detects a first threshold value of an electric storage current in the inductor of the transducer. A second electrical-signal-detecting device, coupled across the fourth switch, detects whether the electric supply current that flows through the fourth switch reaches a second threshold value lower than the first threshold value. The second threshold is derived from the electric storage current.

ENERGY HARVESTING INTERFACE WITH IMPROVED IMPEDANCE MATCHING, METHOD FOR OPERATING THE ENERGY HARVESTING INTERFACE, AND ENERGY HARVESTING SYSTEM USING THE ENERGY HARVESTING INTERFACE

PRIORITY CLAIM

[0001] This application claims priority to Italian Application for Patent No. TO2014A000128 filed Feb. 14, 2014, the disclosure of which is incorporated by reference.

TECHNICAL FIELD

[0002] The present invention relates to an energy harvesting interface with improved impedance matching, a method for operating the energy harvesting interface, and an energy harvesting system comprising the energy harvesting interface.

BACKGROUND

[0003] As is known, systems for harvesting energy (also known as "energy-scavenging systems") from intermittent environmental-energy sources (i.e., ones that supply energy in an irregular way) have aroused and continue to arouse considerable interest in a wide range of technological fields. Typically, energy harvesting systems are configured to harvest, store, and transfer energy generated by mechanical or thermal sources to a generic load of an electrical type.

[0004] Low-frequency vibrations, such as, for example, mechanical vibrations of disturbance in systems with moving parts may be a valid source of energy. The mechanical energy is converted, by one or more appropriate transducers (for example, piezoelectric or electromagnetic devices) into electrical energy, which may be used for supplying an electrical load. In this way, the electrical load does not require batteries or other supply systems, which are cumbersome and present a low resistance in regard to mechanical stresses.

[0005] FIG. **1** is a schematic illustration in the form of functional blocks of an energy harvesting system of a known type.

[0006] FIG. **2** shows, according to a simplified circuit representation, the energy harvesting system of FIG. **1**.

[0007] The energy harvesting system of FIG. **1** comprises: a transducer **2**, for example of an electromagnetic or piezoelectric type, subject in use to environmental mechanical vibrations and configured to convert mechanical energy into electrical energy, typically into AC (alternating current) voltages; a scavenging interface **4**, for example comprising a diode-bridge rectifier circuit (also known as Graetz bridge), configured to receive at input the AC signal generated by the transducer **2** and supplying at output a DC (direct current) signal for charging a capacitor **5** connected to the output of the rectifier circuit **4**; and a DC-DC converter **6**, connected to the capacitor **5** for receiving at input the electrical energy stored by the capacitor **5** and supplying it to an electrical load **8**. Thus, the capacitor **5** has the function of an element for storing energy, which is made available, when required, to the electrical load **8** for operation of the latter.

[0008] This type of interface, which operates as a peak detector, presents some drawbacks. The efficiency of the system **1** of FIG. **1** is markedly dependent upon the signal generated by the transducer **2**. In the absence of the DC-DC converter **6**, the efficiency rapidly drops to zero (i.e., the system **1** is unable to harvest environmental energy) when the amplitude of the signal of the transducer **2** (signal V_{TRANSD}) assumes a value lower, in absolute value, than $V_{OUT}+2V_{TH\_D}$ where V_{OUT} is the voltage across the capacitor **5**, and V_{TH_D} is the threshold voltage of the diodes that form the energy harvesting interface **4**. As a consequence of this, the maximum energy that may be stored in the capacitor **5** is limited to the value $E_{max}=0.5\cdot C_{OUT}\cdot(V_{TRANSD}{}^{MAX}-2V_{TH\_D})^2$. If the amplitude of the signal V_{TRANSD} of the transducer **2** is lower than twice the threshold voltage V_{TH_D} of the diodes of the rectifier of the energy harvesting interface **4** (i.e., $V_{TRANSD}<2V_{TH\_D}$), then the efficiency of the system **1** is zero, the voltage across the output capacitor **5** is zero, the environmental energy is not harvested, and the electrical load **8** is not supplied.

[0009] When the DC-DC converter **6** (of a boost type) is set between the output capacitor **5** and the electrical load **8**, it is possible to make up for the drop in efficiency. However, in this situation, the current supplied by the transducer and rectified by the diode bridge is not regulated and is not actively controlled. Consequently, the impedance R_{LOAD} represented schematically in FIG. **2** cannot be matched to the series impedance R_S of the transducer **2**. This in any case causes a global loss of efficiency of the system **1**.

[0010] A further solution, which enables active control of the current supplied by the transducer **2**, envisages use of an AC-DC converter. This solution, for example proposed by IEEE TRANSACTIONS ON POWER ELECTRONICS, Vol. 25, No. 8, August 2010, pp. 2188-2199 (incorporated by reference), envisages the use of a closed-loop boost converter that exploits directly the series inductance of the transducer and generates a regulated voltage that charges the output capacitor. It is thus possible to supply the electrical load **8** directly by the output capacitor, without the aid of a DC-DC converter **6** of the type illustrated in FIG. **1**. The control loop enables the voltage on the output capacitor for being kept substantially constant. However, this solution presents some disadvantages. For instance, if the load requires a supply power that exceeds the maximum power that the output capacitor may supply, the regulated output voltage drops to zero in a substantially immediate way. Furthermore, in this condition, the AC-DC converter is unable to make up immediately for the voltage drop on the output capacitor, harvesting further energy for supply of the electrical load. The energy harvesting efficiency is thus jeopardized.

SUMMARY

[0011] Embodiments provide an energy harvesting interface, a method for operating the energy harvesting interface, a system for harvesting environmental energy comprising the energy harvesting interface, and an apparatus comprising the environmental-energy harvesting system that will enable the aforementioned problems and disadvantages for being overcome.

[0012] The energy harvesting interface (in particular, having the configuration of a rectifier circuit) may be connected between an input-signal source (in particular, a variable voltage signal) and an electrical load (with the optional interposition of a DC-DC converter configured to supply to the electrical load a voltage signal having a voltage level accepted by the electrical load). The energy harvesting interface comprises, according to one embodiment, a first switch and a second switch, set in series with respect to one another, connected between an input terminal of the interface and a reference terminal of the interface, set at constant voltage (e.g., ground voltage, in particular 0 V). The interface further comprises a third switch and a fourth switch, set in series with respect to one another, connected between an input terminal of the interface and the reference terminal of the interface on which the energy is harvested.

[0013] The energy harvesting interface further comprises a control logic, coupled to the control terminals of the first and second switches, configured to open/close the first and second switches by an appropriate control signal.

[0014] The energy harvesting interface further comprises, as has been said, additional, third and fourth, switches, each having a control terminal. In use, for a polarity of the transduced input signal, the third and fourth switches are kept closed and are used during steps of detection of the current that flows through them, by the control logic. These detection steps define passage from a condition of storage of energy harvested by the transducer (exploiting the inductor integrated in the transducer itself) to a condition of transfer of said energy at output, for example to a storage capacitor and/or to an electrical load.

[0015] The storage capacitor is coupled to the output of the energy harvesting interface, for example, via diodes or controlled switches. The electrical load may be coupled in parallel to the storage capacitor, said electrical load being supplied by the energy stored in the capacitor.

[0016] As has already been said, a DC-DC converter, of buck, or boost, or buck/boost type may be optionally set between the capacitor and the electrical load.

[0017] In a first operating condition, and for a first polarity of the transduced voltage, the first and second switches are closed and the energy harvesting interface stores electrical energy; the diode guarantees that during this operating condition the energy will not flow to the storage capacitor.

[0018] In a second operating condition, and for the first polarity of the transduced voltage, the first switch is opened and the second switch is kept closed; the capacitor is charged by the electrical energy previously stored during the first operating condition and transferred through the diode.

[0019] In the aforementioned first and second operating conditions, the third and fourth switches are kept closed (i.e., ON).

[0020] Passage from the first operating condition to the second operating condition, and vice versa, is cyclic. When the transduced voltage has a second polarity opposite to the first polarity (e.g., the first polarity is positive, and the second polarity is negative), the above operations are carried out in a similar way by appropriately controlling the third and fourth switches and keeping the first and second switches closed (ON).

[0021] The temporal duration of the first and second operating conditions is calculated by appropriate blocks for detecting the current that flows between the inputs of the energy harvesting interface and the reference terminal. These values are then supplied to the control logic that controls the switches according to one aspect.

[0022] The energy harvesting interface is described in detail with reference to an application thereof, in particular as rectifier circuit of an energy harvesting system set between a voltage source and a storage element and/or an electrical load.

BRIEF DESCRIPTION OF THE DRAWINGS

[0023] For a better understanding of the present invention, preferred embodiments thereof are now described, purely by way of non-limiting example and with reference to the attached drawings, wherein:

[0024] FIG. **1** shows an energy harvesting system according to a known embodiment;

[0025] FIG. **2** shows a circuit equivalent to the energy harvesting system of FIG. **1**;

[0026] FIGS. **3**A and **3**B show an energy harvesting system comprising a circuit of an energy harvesting interface that may operate according to the steps of the method of FIG. **11**, according to respective embodiments;

[0027] FIGS. **4**A and **4**B show the energy harvesting system of FIG. **3**A or **3**B in respective operating conditions, following one another in time;

[0028] FIGS. **5**A-**5**C show, using the same time scale, the time plot of current signals of the energy harvesting system of FIG. **3**A or FIG. **3**B in the operating conditions of FIGS. **4**A and **4**B;

[0029] FIG. **6** shows the plot of the coupling factor between the transducer and the harvesting-interface circuit of FIG. **3**A or FIG. **3**B, as operating parameters vary;

[0030] FIG. **7** shows the energy harvesting system of FIG. **3**A or FIG. **3**B in greater detail, according to one embodiment;

[0031] FIG. **8** shows a current detector used in the energy harvesting system of FIG. **7**;

[0032] FIG. **9** shows a further current detector used in the energy harvesting system of FIG. **7**;

[0033] FIG. **10** shows the energy harvesting system of FIG. **3**A or FIG. **3**B in greater detail, according to a further embodiment;

[0034] FIG. **11** shows, by a flowchart, steps of a method for operating the energy harvesting system of FIG. **3**A, **3**B, **7** or **10**;

[0035] FIG. **12** shows an energy harvesting system according to a further embodiment;

[0036] FIG. **13** shows, by a flowchart, steps of a method for operating the energy harvesting system of FIG. **12**;

[0037] FIG. **14** shows a vehicle comprising the energy harvesting system according to any one of the embodiments; and

[0038] FIG. **15** shows an item of footwear comprising the energy harvesting system according to any one of the embodiments.

DETAILED DESCRIPTION OF THE DRAWINGS

[0039] FIG. **3**A shows an energy harvesting system **20** comprising a rectifier circuit **24**, according to one embodiment.

[0040] In general, the energy harvesting system **20** comprises: a transducer **22** (similar to the transducer **2** of FIG. **1**) including its own output terminals **22'**, **22"**; the rectifier circuit **24**, including a first input terminal **25'** and a second input terminal **25"**, electrically coupled, respectively, to the output terminals **22'**, **22"** of the transducer **22**, a first output terminal **26'**, and a reference terminal **26"**; and a storage element **27**, for example a capacitor, connected between the first output terminal **26'** and the reference terminal **26"** of the rectifier circuit **24**, and configured to store electrical charge supplied at output from the rectifier circuit **24**. According to one embodiment, the reference terminal **26"** is a ground-voltage reference terminal GND, for example equal to approximately 0 V. Other reference voltages may be used.

[0041] The transducer **22** is, for example, an electromagnetic transducer, and is represented schematically for including a voltage generator **22***a*, configured to supply a voltage V_{TRANSD}, an inductor **22***b* (typical of the electromagnetic transducer) having an inductance L_S, and a resistor **22***c* having a resistance R_S, connected in series to the inductor **22***b*.

[0042] On the output of the rectifier circuit **24**, in parallel with the storage element **27**, there may be connected an electrical load **28**, configured for being supplied by the charge stored in the storage element **27** or by means, for example, of a DC-DC converter (not illustrated in the figures) in the case where the electrical load requires a voltage value different from the voltage generated at output from the rectifier circuit **24**.

[0043] Connected in series together between the first input terminal **25'** and the reference terminal **26"** of the rectifier circuit **24** are a high-voltage (HV) switch **30***a* and a low-voltage (LV) switch **30***b*, in particular of the voltage-controlled type. The switches **30***a* and **30***b* are, for example, N-channel field-effect transistors (FETs).

[0044] The HV switch **30***a* is a device that is able to withstand high voltages. According to one embodiment, the HV switch **30***a* is a DMOS transistor configured to operate with gate-to-drain voltages (V_{GD}) and drain-to-source voltages (V_{DS}) ranging between 30 and 50 V, for example 40 V.

[0045] In addition to DMOSs, it is likewise possible to use drift MOSs and drain extension MOSs, which are transistors that may withstand high voltages between drain and source terminals, and between gate and drain terminals. It may be noted that the range of voltages indicated is purely indicative and non-limiting. Technologies configured to withstand voltages higher than 50 V are known and under development, and may likewise be used in the context of the present circuit.

[0046] The LV switch **30***b* is a low-voltage device. According to one embodiment, the LV switch **30***b* is a CMOS transistor configured to operate with gate-to-source voltages (V_{GS}) ranging, for example, between 1 and 5 V, in particular 2.5-3.6 V, for example 3.3 V. Other technologies for low-voltage transistors envisage slightly higher operating voltages, for example in the region of 4-5 V.

[0047] It is evident that the values appearing indicate a possible embodiment, and vary according to the technology used for the transistors and to the specific application.

[0048] The first input terminal **25'** is electrically coupled to the first output terminal **26'** by a diode **36**. The diode **36** is chosen for having a low forward threshold voltage, in the region of 0.6-0.7 V, for maximizing the efficiency of the rectifier, above all in the steps where the voltage stored on the output capacitor is low.

[0049] According to an alternative embodiment (not illustrated), the diode **36** may be replaced by a MOSFET, for example, of the N-channel type. As is known, a MOSFET has an internal diode (parasitic diode). In this case, the MOSFET may be operated in an active way (by actively controlling turning-on and turning-off of the MOSFET), or in a passive way (by turning off the MOSFET and exploiting the internal parasitic diode).

[0050] Furthermore, the rectifier circuit **24** comprises a further HV switch **31***a* and a further LV switch **31***b*, connected together in series and electrically coupled between the second input terminal **25"** and the reference terminal **26"** of the rectifier circuit **24**. The switches **31***a* and **31***b* are similar to the switches **30***a* and **30***b*, and such that the HV switch **31***a* is a device that is able to withstand high gate-to-drain voltages and drain-to-source voltages (for example 30-50 V, in particular 40 V), whereas the LV switch **31***b* is a low-voltage device, for example a CMOS, which is able to withstand low gate-to-source voltages (for example, 1-5 V, in particular 2.5-3.6V, even more in particular 3.3 V). Other technologies for low-voltage transistors envisage slightly higher operating voltages, for example in the region of 4-5 V.

[0051] The second input terminal **25"** is electrically coupled to the first output terminal **26'** by a diode **38**, similar to the diode **36**. According to an alternative embodiment (not illustrated), the diode **38** may be replaced by a MOSFET, for example an N-channel MOSFET. As is known, a MOSFET has an internal diode (parasitic diode). In this case, said MOSFET may be operated in a active way (by actively controlling turning-on and turning-off of the MOSFET), or in a passive way (by turning off the MOSFET and exploiting the internal parasitic diode).

[0052] For simplicity of description, the HV switches **30***a* and **31***a* will hereinafter be referred to, respectively, as "high-voltage (HV) transistors **30***a* and **31***a*", without this implying any loss of generality, and the LV switches **30***b* and **31***b* be referred to, respectively, as "low-voltage (LV) transistors **30***b* and **31***b*", without this implying any loss of generality.

[0053] Likewise, the terms "transistor closed" or "transistor ON" will hereinafter refer to a transistor biased so to enable conduction of electric current between its source and drain terminals, i.e., configured to behave as a closed switch, and the terms "transistor open" or "transistor OFF" will hereinafter refer to a transistor biased so not to enable conduction of electric current between its source and drain terminals, i.e., configured to behave ideally as an open or inhibited switch.

[0054] FIG. **3**B shows the energy harvesting system **20** of FIG. **3**A, where the switches have been replaced by respective transistors. Each transistor is further represented with its own internal diode (parasitic diode).

[0055] With reference to FIG. **3**B, the drain terminal D of the HV transistor **30***a* is connected to the first input terminal **25'** of the rectifier circuit **24**, whereas the source terminal S of the HV transistor **30***a* is connected to the drain terminal D of the LV transistor **30***b*; the source terminal S of the LV transistor **30***b* is instead connected to the reference terminal **26"**. The diode **36** has its cathode electrically coupled to the output terminal **26'** of the rectifier circuit **24** and its anode electrically coupled to the first input terminal **25'** of the rectifier circuit **24**.

[0056] As regards the HV transistor **31***a* and LV transistor **31***b*, these are connected between the second input terminal **25"** and the reference terminal **26"** of the rectifier circuit **24** so that the source terminal S of the LV transistor **31***b* is connected to the reference terminal **26"**, the drain terminal D of the HV transistor **31***a* is connected to the second input terminal **25"**, and the remaining drain terminal D of the LV transistor **31***b* and source terminal S of the HV transistor **31***a* are connected together.

[0057] The diode **38** has its cathode electrically coupled to the output terminal **26'** of the rectifier circuit **24** and its anode electrically coupled to the second input terminal **25"** of the rectifier circuit **24**. During positive half-cycles of the input voltage V_{IN}, the voltage is rectified by appropriately driving the HV transistor **30***a*, keeping the transistors **30***b*, **31***a*, **31***b* in the ON state. Instead, during negative half-cycles of the input voltage V_{IN}, the voltage is rectified by appropriately driving the HV transistor **31***a*, keeping the transistors **31***b*, **30***a*, **30***b* in the ON state.

[0058] According to one embodiment, the rectifier circuit **24** further comprises a control circuit and a control logic, designated in FIG. **3**A or FIG. **3**B by the reference numbers **60** and **70**, and better described with reference to FIGS. **8** and **9**. Furthermore, the control logic **60** implements the steps of the method of FIG. **11**.

[0059] In use, for example for positive values of the voltage V_{IN}, the HV transistor **30***a* and the LV transistor **30***b* are kept ON for at least a time interval T_{DELAY} for storing energy in the inductor **22***b* (situation illustrated schematically in FIG. **4**A). During this step, storage of the energy in the inductor **22***b* is guaranteed by the fact that the diode **36** does not conduct. Furthermore, also the transistors **31***a* and **31***b* are kept in the ON state.

[0060] Then, when the time interval T_{DELAY} has elapsed and the energy stored (current flowing) in the inductor **22***b* has reached a minimum threshold value I_{TH}, the HV transistor **30***a* is turned off. A current may thus flow from the inductor **22***b*, through the diode **36**, to the storage element **27**/electrical load **28**. This situation is illustrated schematically in FIG. **4**B.

[0061] As has been said, the input signal V_{IN} is a variable signal, i.e., having a polarity that varies in time. For negative polarities of V_{IN}, what has been described with reference to FIGS. **4**A and **4**B is in any case valid by controlling in a similar way the transistors **31***a* and **31***b*. The steps of control of these transistors are not herein described for brevity, but are apparent to the person skilled in the branch on the basis of what has so far been described.

[0062] According to one embodiment, in both of the operating conditions of FIGS. **4**A and **4**B, for positive polarities of the input voltage V_{IN}, the LV transistor **30***b* is always kept closed, and the control logic **60** drives just the HV transistor **30***a* into the open/closed state. Likewise, for negative polarities of the input voltage V_{IN}, the control logic **60** drives just the HV transistor **31***a* into the open/closed state, whereas the LV transistor **31***b* is always kept closed. This situation is schematically represented in FIG. **3**B, which shows a voltage generator, configured to generate a voltage V_{DD}, coupled to the control terminals G of the LV transistors **30***b* and **31***b*. The voltage V_{DD} is chosen with a value such as to drive the LV transistors **30***b* and **31***b* into the closed state.

[0063] During the step of FIG. **4**B, where the current stored in the inductor **22***b* is transferred at output on the storage element **27** by the diode **36** (or alternatively the diode **38**, according to the polarity of the input voltage V_{IN}), an increase in the output voltage V_{OUT} is noted.

[0064] Hereinafter, operation of the rectifier **24** is described more fully with reference to a circuit model valid for one polarity (in particular, the positive polarity) of the input signal V_{IN}, for greater simplicity and clarity of description. As has been said, what has been described may in any case be readily applicable to control of the transistors **31***a* and **31***b*, in the case of negative polarity of the input signal V_{IN}.

[0065] FIG. **4**A shows a circuit equivalent to the circuit of FIG. **3**A or FIG. **3**B, for positive half-waves of the input voltage V_{IN}. The diode **36**, in this condition, does not conduct. The transistors **30***a* and **30***b* are ON. In this operating condition, the transistors **30***a* and **30***b* are ideally replaced by respective resistors which have a resistance R^{HV}_{ON} and, respectively, R^{LV}_{ON} (ON-state resistance of the transistors **30***a* and **30***b*).

[0066] The current I_L that flows in the inductor **22***b* is equal to the current I_{ON} that traverses the transistors **30***a* and **30***b* in the ON state. The value of the current I_L increases until it reaches a maximum, or peak, value I_p (see the graph of FIG. **5**A).

[0067] The current I_{ON} reaches the peak value I_p at time $t=t_c=T_{DELAY}$. For simplicity, it is assumed that the starting instant t_0 is 0 μs.

[0068] Once the time interval T_{DELAY} has elapsed and assuming that the current I_L that flows in the inductor **22***b* has reached a value equal to, or higher than, the threshold value I_{TH}, the operating condition represented schematically in FIG. **4**B is reached.

[0069] The time interval T_{DELAY} is the interval between the instant of closing of the HV transistor **30***a* (at time t_0) and the instant of opening of the HV transistor **30***a* (at time t_c).

[0070] The value of threshold current I_{TH} is chosen on the basis of the values of the maximum or of the minimum short-circuit current that the transducer supplies. It is the ratio between the maximum or minimum voltage V_{TRANSD} and the series resistance R_S, which depends on the application of the rectifier circuit **24**.

[0071] These values depend upon the characteristics of the transducer **22** and upon the environmental stresses to which the transducer **22** is subjected. In particular, the value of threshold current I_{TH} is chosen much lower than the peak value I_p that is expected for being reached in the application in which the rectifier circuit **24** is used. For instance, assuming that peak values I_p of approximately 150 mA are reached, the threshold I_{TH} may be chosen between approximately 5-10 mA. It is for being noted that the choice of a threshold current I_{TH} too close to the peak value I_p entails a low efficiency. In fact, according to what has been described, current is transferred at output only when the threshold I_{TH} is exceeded; all the portions of the signal V_{TRANSD} that generate a current with peak value $I_p<I_{TH}$ do not give a contribution of charge transferred at output.

[0072] With reference to FIG. **4**B, at time t_c, the HV transistor **30***a* is opened, and the diode **36** starts to conduct. The current I_L that flows from the inductor **22***b* to the output **26'** of the rectifier **24** is the current I_{OUT} that charges the capacitor **27**. In this step, the current in the inductor **22***b* decreases with a constant slope, until it reaches the predefined value I_{OFF} (at time t_{max}, see again FIG. **5**A).

[0073] I_{OFF} is a constant value, given by I_p/K, where K is a constant higher than 1 (chosen as explained hereinafter). FIG. **5***a* shows the plot of the current I_L at time t (in microseconds). The curve of the current I_L reaches the peak value I_p at the instant t_c, where the HV transistor **30***a* is opened (see FIG. **5**B).

[0074] Then, between t_c and t_{max} (time interval T_{CHARGE}) the current I_L decreases until it reaches the value $I_{OFF}=I_p/K$.

[0075] FIG. **5**B shows, using the same time scale as that of FIG. **5**A, the plot of the current I_{ON} that flows through the HV transistor **30***a* during the step of FIG. **4**A of charging of the inductor **22***b*. In the time interval t_0-t_c, the current I_{ON} follows the same plot as that of the current I_L; at the instant t_c, the HV transistor **30***a* is opened and consequently the current I_{ON} drops to zero.

[0076] FIG. **5**C shows, using the same time scale as that of FIGS. **5**A and **5**B, the plot of the output current I_{OUT}. The current I_{OUT} remains at a zero value in the time interval t_0–t_c to reach the peak value I_p at the instant t_c in which the capacitor **27** is electrically coupled to the inductor **22***b*. Then, between t_c and t_{max} (within the time interval T_{CHARGE}), the energy stored in the inductor **22***b* supplies and charges the capacitor **27**.

[0077] At time t_{max}, when the current that flows to the capacitor **27** reaches the threshold value I_{OFF}, the HV transistor **30***a* is closed so that the inductor **22***b* charges again, as has already been described. The steps of charge and discharge of the inductor **22***b* (and, consequently, of supply of the capacitor **27**/load **28**) repeat in a cyclic way.

[0078] The integral of the curve of I_{OUT} (FIG. **5**C) between time t_c and time t_{max} indicates the charge Q_{CYCLE} transferred between the input and the output of the rectifier **24** in the time interval T_{CHARGE}. In order to maximize the efficiency of transfer of charge between the input and the output of the rectifier **24**, it is expedient to maximize the value of the power P_{CYCLE} transferred at output from the rectifier circuit **24** in each cycle of charge/discharge of the inductor **22***b*. The power P_{CYCLE} is defined as $P_{CYCLE}=V_{OUT}\cdot I_{CYCLE}$, where I_{CYCLE} is given by $I_{CYCLE}=Q_{CYCLE}/T_{CYCLE}$, where T_{CYCLE} is the time interval between t_0 and t_{max} ($T_{CYCLE}=T_{DELAY}+T_{CHARGE}$).

[0079] It is noted that P_{CYCLE} is given by the following relation (where I_{ON} assumes the peak value I_p)

$$P_{CYCLE} = \frac{\frac{I_{ON} + I_{OFF}}{2} \cdot T_{CHARGE}}{T_{DELAY} + T_{CHARGE}} \cdot V_{OUT}$$

[0080] From the foregoing relation it may be noted how the power P_{CYCLE} is a function of the design parameters T_{DELAY} and K, and of the external variables V_{TRANSD} (voltage of the transducer, not predictable) and V_{OUT} (voltage across the capacitor **27**, which is not predictable either). Maximizing the value of P_{CYCLE} thus means finding the optimal values of T_{DELAY} and K such that the curve of P_{CYCLE} reaches a maximum value, or a value close to the maximum, or an optimal value definable according to the particular application and design requirements.

[0081] The curve of P_{CYCLE} reaches an optimal value when the output of the transducer **22** and the input of the rectifier circuit **24** show the same impedance (they are, that is, matched). The best coupling efficiency η_{COUPLE} between the transducer **22** and the rectifier circuit **24** is given by $P_{CYCLE}^{OPT}/P_{TRANSD}^{MAX}$, where P_{CYCLE}^{OPT} is the value of P_{CYCLE} calculated with optimal values of T_{DELAY} and K, and P_{TRANSD}^{MAX} is given by $(V_{TRANSD})^2/4R_S$.

[0082] Optimization of the value of P_{CYCLE} enables an optimal value of the time interval T_{DELAY} and of the factor K for being obtained (and vice versa) as a function of the value of V_{TRANSD} and V_{OUT}. However, the dependence of T_{DELAY} upon V_{TRANSD} and V_{OUT} is irrelevant for practical purposes, and the value of coupling efficiency η_{COUPLE} reaches values higher than 95% for values of V_{TRANSD} and V_{OUT} of practical interest.

[0083] FIG. **6** shows the plot of the coupling efficiency η_{COUPLE} as the values T_{DELAY} and K vary. The graph of FIG. **6** may be easily obtained from the expression of P_{CYCLE} by varying the parameters T_{DELAY} and K (fixing the values of the external variables V_{TRANSD} and V_{OUT}). To each value of η_{COUPLE} there corresponds a pair of values T_{DELAY} and K. It is thus possible to obtain automatically the pair of optimal values T_{DELAY} and K to obtain a desired value of coupling efficiency η_{COUPLE}. In the graph of FIG. **6**, the darker areas are the ones in which the value of coupling efficiency η_{COUPLE} is higher; instead, the lighter areas are the ones in which the value of coupling efficiency η_{COUPLE} is lower (low values of T_{DELAY} and high values of K, or high values of T_{DELAY} and low values of K).

[0084] In the specific case, a good compromise for the choice of the values of T_{DELAY} and K, in order to have contained consumption levels and good coupling efficiency, is obtained by choosing $T_{DELAY}=40$ μs and K=1.75. It is, however, evident that the choice of the values of T_{DELAY} and K depends upon the field of application, and these values may thus be chosen freely according to the need (in general with K≥1).

[0085] FIG. **7** shows, by functional blocks, a control circuit **70** for driving the HV transistor **30***a* in order to implement the operating conditions of FIGS. **4***a* and **4***b*. The control circuit **70** operates, in particular, for positive half-waves (V_{IN}^+) of the input signal V_{IN}. The LV transistors **30***b* and **31***b* are biased at constant voltage V_{DD}, for being kept always in the ON state. The value of the voltage V_{DD} is thus chosen on the basis of the characteristics of these transistors, with the purpose of driving them into the ON state.

[0086] In order to drive the HV transistor **31***a* for negative half-waves of the input signal V_{IN}, a circuit architecture is used similar to the one illustrated for the control circuit **70** (see, for example, FIG. **10**).

[0087] In greater detail, the control circuit **70** comprises a first current detector **72**, coupled between the source terminal S and the drain terminal D of the LV transistor **30***b*, for detecting (during the step of FIG. **4**A) the instant in which the current I_{ON} that flows through the LV transistor **30***b* (and, consequently, also through the HV transistor **30***a*) exceeds the threshold I_{TH}. When this condition is detected, and the interval T_{DELAY} has elapsed, the control logic **60** drives the HV transistor **30***a* into inhibition, thus controlling passage to the operating condition of FIG. **4**B. In addition, the current detector **72** participates in generation, in the step of FIG. **4**A, of a scaled copy I_{ON}/K of the current that flows in the LV transistor **30***b*, as illustrated more clearly hereinafter.

[0088] FIG. **8** shows in greater detail the first current detector **72**, according to one embodiment. With reference to FIG. **8**, a first portion of the current detector **72** comprises a comparator **86** configured to receive at input, on its non-inverting terminal, the voltage signal present on the source terminal S of the HV transistor **30***a* (or likewise on the drain terminal of the LV transistor **30***b*) and, on its inverting terminal, a voltage signal V_{TH} identifying the threshold I_{TH} (by an appropriate voltage-to-current conversion, in itself obvious). The comparator **86** generates at output a digital signal V_{OUT_TH}, which assumes the low logic level "0" when $I_{ON}<I_{TH}$ and the high logic level "1" when $I_{ON}\geq I_{TH}$ (or vice versa). In greater detail, the comparator **86** is configured to receive, at input on its non-inverting terminal, the voltage signal present on the source terminal of the HV transistor **30***a* (signal V_{IN}^+), and, at input on its inverting terminal, a threshold-voltage signal V_{TH} such that $V_{TH}=I_{TH}\cdot(R^{HV}_{ON}+R^{LV}_{ON})$ where, as has already been said, R^{HV}_{ON} is the ON-state resistance of the HV transistor **30***a*, and R^{LV}_{ON} is the ON-state resistance of the LV transistor **30***b*. When the voltage on the source terminal of the HV transistor **30***a* exceeds the threshold V_{TH}, the output of the comparator **86** changes state to signal that the threshold has been exceeded (and thus to indicate that $I_L=I_{ON}\geq I_{TH}$).

[0089] The signal at output from the comparator **86** is supplied to the control logic **60**. The control logic **60** monitors the duration of the time interval T_{DELAY} and, when the time interval T_{DELAY} has elapsed, turns off the HV transistor **30***a*.

[0090] Passage of the time interval T_{DELAY} may alternatively be monitored by the comparator **86**. In this case, the signal at output from the comparator **86** assumes a high logic level when $I_{ON} \geq I_{TH}$ and $t \geq T_{DELAY}$, and the control logic **60** turns off the HV transistor **30***a* at the rising edge of the digital signal generated by the comparator **86**.

[0091] A second portion of the current detector **72** comprises a negative feedback loop including a comparator **89**, which controls the current that flows on an output branch **90** of the current detector **72**, by acting on the control terminal of a transistor **91** belonging to the output branch **90**. The output branch **90** further comprises an additional transistor **92**, connected in series to the transistor **91**. Note that the transistor **92** is a low-voltage transistor, for example a CMOS. In particular, the transistor **92** is configured to operate with gate-to-source voltages in the range 1-5 V, in particular 2.5 V-3.6 V, for example at 3.3 V. Other low-voltage-transistor technologies envisage slightly higher operating voltages, for example in the region of 4-5 V.

[0092] In particular, the transistor **92** is of the same type as the LV transistor **30***b*, but is sized so that it has dimensions (measured in terms of width-to-length aspect ratio W/L) F times lower than the LV transistor **30***b* and is configured to conduct a current F times lower than the value assumed by I_{ON} (current that flows through the LV transistor **30***b*). The LV transistor **30***b* and the transistor **92** further have their respective control terminals connected together and biased at the voltage V_{DD}.

[0093] The negative feedback loop of the current detector **72** controls the gate voltage of the transistor **91** so that the drain voltage of the transistor **92** will be equal to the voltage across the capacitor **88**. In use, current always flows in the output branch **90**. In the step of FIG. **4**A, the current is variable and equal to I_{ON}/F, whereas in the step of FIG. **4**B the current is constant and equal to I_p/F. Sizing of the transistor **92** guarantees that the current that flows in the output branch **90** is a fraction **1**/F of the current I_{ON} (or of its peak value I_p, as has been said).

[0094] The negative feedback, obtained by the comparator **89** and the transistor **91**, ensures that the drain voltages of the transistors **30***b* and **92** will be identical. Consequently, the current that flows through the transistor **92** assumes values equal to the value of I_{ON} scaled by the factor F (when I_{ON} reaches the peak value I_p, this current will be equal to I_p/F). There is thus generated a scaled copy of the factor F of the peak current I_p. Since both of the transistors **30***b* and **92** are low-voltage transistors (e.g., CMOSs) they provide excellent matching properties so that the factor F is minimally affected by problems of mismatch between the transistors **30***b* and **92** (as, instead, would be the case, where the transistors **30***b* and **92** were high-voltage transistors). This enables a scaled copy of the peak current I_p for being obtained that is stable and with reproducible value.

[0095] The negative feedback provided by the comparator **89** ensures that the signal at input to the non-inverting terminal of the comparator **89** and the signal at input to the inverting terminal of the comparator **89** are equal so that the LV transistor **30***b* and the transistor **92** have the same source-to-drain and drain-to-gate voltages.

[0096] A current mirror **90'**, made in a per se known manner, is used for repeating the current I_{ON}/F that flows in the branch **90** and supplying it at output from the current detector **72**.

[0097] The first current detector **72** further comprises a transistor **87** having a drain terminal common to the source terminal of the HV transistor **30***a*, and its source terminal coupled to a capacitor **88** (the second terminal of the capacitor **88** is connected to the reference voltage GND). The control terminal G of the transistor **87** is connected to the control terminal G of the HV transistor **30***a* and to a biasing terminal at the voltage V_{GATE_LS}. In this way, the HV transistor **30***a* and the transistor **87** are driven into the ON/OFF state at the same time, using the same signal V_{GATE_LS} (in particular, with reference to FIG. **7**, the signal generated at output from a first driving device **76**).

[0098] During the time interval T_{DELAY} (situation of FIG. **4**A), the HV transistor **30***a* is ON (the signal V_{GATE_LS} has a value such as to drive the HV transistor **30***a* into the ON state). In the same way, also the transistor **87** is ON. The capacitor **88** is consequently charged at the voltage present on the first input terminal **25'** of the rectifier circuit **24** (in the figure, the voltage across the capacitor **88** is designated by V_{C_SAMPLE}).

[0099] The comparator **89** is connected to the source terminal of the transistor **87** and, when the transistor **87** is ON, it receives at input (on its non-inverting terminal) the voltage of the drain terminal of the LV transistor **30***b*, and at input (on its inverting terminal) the signal present on the drain terminal of the transistor **92** and on the source terminal of the transistor **91**; the output of the comparator **89** is coupled to the control terminal G of the transistor **91**. The transistor **91** is always ON; the comparator **89** biases the control terminal of the transistor **91** so that the current I_{ON}/F flows in the branch **90**, as is desired.

[0100] When the HV transistor **30***a* is OFF, also the transistor **87** is OFF, and the capacitor **88** is in the floating state, ensuring, during the time interval T_{CHARGE}, a current having a practically constant value through the transistor **92** and equal to I_p/F.

[0101] In fact, during the step of supply of the capacitor **27**/load **28**, the capacitor **88** ensures maintenance of the voltage V_{C_SAMPLE} across it, guaranteeing a substantially constant input signal (but for the losses of the capacitor **88**) on the non-inverting input of the comparator **89**. This enables generation of the current I_{ON}/F for being kept unaltered on the output branch **90** of the first current detector **72** during the step of FIG. **4**B (in this step, the current I_{ON} has reached the peak value I_p, and consequently a current I_p/F flows in the output branch **90** of the first current detector **72**).

[0102] To return to FIG. **7**, the control circuit **70** further comprises a second current detector **74**, coupled between the source terminal S and the drain terminal D of the LV transistor **31***b*.

[0103] The second current detector **74** is configured to detect the value of current I_{OUT} that flows through the LV transistor **31***b* during the operating step of FIG. **4**B, i.e., following upon charging of the capacitor **27**. In particular, the second current detector **74** co-operates with the control logic **60** in order to detect whether the current $I_L = I_{OUT}$ through the LV transistor **31***b* reaches the minimum value envisaged $I_{OFF} = I_p/K$. The output signal of the second current detector **74**, which indicates the value of current through the LV transistor **31***b*, is supplied at input to the control logic **60**.

[0104] The second current detector **74** receives at input the current I_{ON}/F (generated by the first current detector **72**, as described previously), and switches when the current through the LV transistor **31***b* reaches the minimum value envisaged, given by $I_{OFF}=I_p/K$.

[0105] The control circuit **70** further comprises the first driving device **76** and a second driving device **78**, which are coupled, respectively, between the control logic **60** and the control terminal G of the HV transistor **30***a* and between the control logic **60** and the control terminal G of the HV transistor **31***a*. The first driving device **76** and the second driving device **78** are, in themselves, of a known type, and are configured to drive the transistors **30***a*, **31***a* into the opening/closing condition on the basis of a respective control signal received from the control logic **60**. In particular, in the operating condition of FIG. **4**A (positive half-wave of the transduced signal V_{TRANSD}), the control logic **60** drives, via the first driving device **76**, the HV transistor **30***a* into the ON state and, via the second driving device **78**, the HV transistor **31***a* into the ON state. On the basis of the signal generated at output from the first current detector **72**, the control logic **60** detects whether the current $I_L=I_{ON}$ has reached (and/or exceeded) the threshold value I_{TH} and whether the time T_{DELAY} has elapsed: if so, the control logic **60** drives, via the first driving device **76**, the HV transistor **30***a* into the OFF state and, via the second driving device **78**, maintains the HV transistor **31***a* in the ON state. Then, the control logic **60** monitors, on the basis of the signal received from the second current detector **74**, the value of the current $I_L=I_{OUT}$ through the LV transistor **31***b* to control passage from the operating condition of supply of the capacitor **27**/load **28** (FIG. **4**B) to the operating condition of storage of energy in the inductor **22***b* (FIG. **4***a*).

[0106] FIG. **9** shows the second current detector **74** in greater detail.

[0107] The current detector **74** is electrically coupled to a node X set between the drain terminal D of the LV transistor **31***b* and the source terminal S of the HV transistor **31***a*, for receiving at input an intermediate voltage signal V_X present on said node X. The current detector **74** includes a coupling transistor **85**, of an N type, having its drain terminal coupled to the node X and its gate terminal biased at voltage V_{DD}. As in the case mentioned previously, the voltage V_{DD} is chosen with a value such as to drive into the ON state the coupling transistor **85**, which thus remains always ON during the operating steps of the energy harvesting system.

[0108] The current detector **74** further includes a comparator **84**, having an inverting input electrically coupled to the reference voltage GND and a non-inverting input electrically coupled to the source terminal of the coupling transistor **85**. In other words, the non-inverting input of the comparator **84** and the source terminal of the coupling transistor **85** are coupled to the same node Y, having a voltage V_Y. The node Y further receives the current signal I_{ON}/F generated at output by the first current detector **72**.

[0109] The comparator **84** generates at output a signal $V_{OUTCOMP}$ that is configured to assume alternatively a high logic value "1" and a low logic value "0" according to the value assumed by the signal V_Y.

[0110] The coupling transistor **85** presents in use an internal resistance (channel resistance, or ON-state resistance) $R_{DMY}=G\cdot R_{LS}$, where R_{LS} is the internal resistance (channel resistance, or ON-state resistance) of the LV transistor **31***b*. In other words, the resistance R_{DMY} is chosen equal to a multiple G of R_{LS}.

[0111] In use, it is found that the voltage V_X on the node X is given by:

$$V_X=-I_L\cdot R_{LS}$$

[0112] and the voltage V_Y on the node Y is given by

$$V_Y=V_X+G\cdot R_{LS}\cdot I_{ON}/F$$

Thus,

$$V_Y=-I_L\cdot R_{LS}+G/F\cdot I_{ON}\cdot R_{LS}$$

[0113] The output $V_{OUTCOMP}$ of the comparator **84** changes its logic value when the voltage V_Y reaches the threshold defined by the reference voltage GND, in this example chosen equal to 0 V. We obtain that the output of the comparator **84** changes its logic value when $V_Y=0$. From this condition it follows that the output $V_{OUTCOMP}$ identifies the fact that, the value of scaled copy I_{ON}/K has been reached by the output current $I_L=I_{OUT}$. In fact, setting $V_Y=0$ in the previous equation, we have that the threshold current I_L (i.e., the threshold current I_{OUT}) is equal to $(G/F)\cdot I_{ON}$. The constant K is consequently equal to F/G. It is pointed out that, as illustrated previously, in use, the value of I_{ON} at which there occurs passage from the step of FIG. **4**A to the step of FIG. **4**B is equal to I_p. Consequently, we find that the change of logic value of the signal $V_{OUTCOMP}$ identifies that the threshold $(G/F)\cdot I_p=I_p/K$ has been reached.

[0114] With reference once again to FIG. **7**, the signal $V_{OUTCOMP}$ of the comparator **84** is received by the control logic **60**, which controls, on the basis of the value of $V_{OUTCOMP}$ received, passage from the step of FIG. **4**B to the step of FIG. **4**A. For instance, a value $V_{OUTCOMP}$="0" identifies a situation in which the current I_{OUT} has not yet reached the threshold I_{OFF}; instead, a value $V_{OUTCOMP}$="1" identifies a situation in which $V_Y=0$ and the current I_{OUT} has reached the threshold I_{OFF}.

[0115] Preferably, the transistors **31***b*, **92** and **85** are low-voltage transistors manufactured with the same technology (e.g., CMOS technology) so that they guarantee optimal matching properties such that the factor G is minimally affected by problems of mismatch between the transistors **31***b*, **92**, and **85** (as instead would be the case, where both of the transistors were high-voltage transistors). Stabilizing G around a desired value corresponds to stabilizing the values of K and F around the values chosen. The parameter K thus has a minimal spread around the chosen and desired value.

[0116] According to one embodiment, the transistors **92** (FIG. **8**) and **85** (FIG. **9**) are provided in the form of modular transistors. The transistors **92** and **85** may be obtained as a series or parallel combination of the same basic module for minimizing the mismatch between the factors F and G, and thus render the parameter K "stable".

[0117] For instance, the transistor **92** is formed by connecting, in parallel to one another, a plurality of basic modules (each module being a low-voltage MOSFET with aspect ratio W_b/L_b) so that the source terminals of each basic module are electrically connected together to a common source node, and the drain terminals of each basic module are electrically connected together to a common drain node. The gate terminals of each basic module are selectively driven into the ON state or the OFF state to form, in use, the transistor **92**, the aspect ratio W/L of which is a multiple of the aspect ratio W_b/L_b of each basic module. In this way, by turning on/turning off selectively one or more basic modules, it is possible to regulate the total amount of current carried by the transistor **92** and consequently regulate the value of the ratio 1:F between the transistor **92** and the transistor **30***b*.

[0118] A similar solution may be applied to form the transistor **85**, with variable value of G. In this case, it is possible to connect, in parallel to one another, a plurality of series of basic modules of low-voltage MOSFETs, which have the same aspect ratio (for example, W_b/L_b). Each series of basic modules presents, in use, a respective electrical resistance to the passage of the current. By selectively activating/deactivating the series of the basic modules that form the transistor **85**, it is thus possible to regulate the value of electrical resistance represented by the transistor **85** in use. The transistor **85** behaves as a resistor with a variable resistance that may be selected according to the requirement.

[0119] Consequently, the values of F and G may be chosen according to the need, as a function of the value of the parameter K that it is desired to use for the specific application.

[0120] Turning-on/turning-off of the basic modules of the transistors **85** and **92** is performed by the control logic during use. For this purpose, the control logic includes a memory **83** that stores the information regarding which and/or how many basic modules of the transistors **85** and **92** are for being turned on. If the memory **83** is of the re-writeable type, this information may be updated/modified according to the need.

[0121] The transistors **30***b*, **92** and **85** are the components via which we it is possible to control I_{TH}, the factors F and G, and consequently the factor K. By providing them in a modular form, as has been described, they may be readily configured via the memory **83** and appropriate driving devices, for enabling/disabling a certain number of basic modules thus obtaining respective equivalent transistors, which have a desired respective aspect ratio W/L.

[0122] Thus, with just one device, appropriately configured via the information stored in the integrated memory **83**, it is possible to vary freely I_{TH}, T_{DELAY} and K and thus adapt to a very wide range of transducers available on the market.

[0123] With reference to FIG. **10**, a control circuit **70'** is illustrated for driving both of the HV transistors **30***a* and **31***a* into the ON/OFF state in order to implement the operating conditions of charging of the inductor **22***b* and supply of the capacitor **27** (and/or load **28**) for positive half-waves (V_{IN}^+) and negative half-waves (V_{IN}^-) of the input signal V_{IN}.

[0124] Elements of the control circuit **70'** that are similar to elements of the control circuit **70** of FIG. **7** are designated by the same reference numbers and will not be described any further.

[0125] The control circuit **70'** comprises, in addition to what has already been described with reference to the control circuit **70** of FIG. **7**, a third current detector **72'**, and a fourth current detector **74'**.

[0126] The third current detector **72'** is similar to the first current detector **72**, and consequently is not described and illustrated any further in the figures. The third current detector **72'**, unlike the first current detector **72**, is electrically coupled between the reference terminal GND (corresponding to the source terminal of the LV transistor **31***b*) and the drain terminal of the LV transistor **31***b*, and generates at output a current signal $(I_{ON}/F)'$.

[0127] The fourth current detector **74'** is similar to the second current detector **74**, and consequently is not described and illustrated any further in the figures. The fourth current detector **74'**, unlike the second current detector **74**, is electrically coupled between the reference terminal GND (corresponding to the source terminal of the LV transistor **30***b*) and the drain terminal of the LV transistor **30***b*, and further receives at input the current signal $(I_{ON}/F)'$ generated by the third current detector **72'**.

[0128] Operation of the third and fourth current detectors is altogether similar to what has already been described with reference to the first and second current detectors **72** and **74** and consequently is immediately evident to a person skilled in the branch.

[0129] In use, when a positive half-wave of the input signal V_{IN} is detected, the control logic **60** monitors just the signals generated at output from the first signal detector **72** (V_{OUT_TH}) and from the second signal detectors **74** ($V_{OUTCOMP}$) to evaluate passage from the step of charging of the inductor **22***b* to the step of supply of the capacitor **27**/load **28**, and vice versa. Instead, when a negative half-wave of the input signal V_{IN} is detected, the control logic **60** monitors just the signals generated at output from the third signal detector **72'** (V_{OUT_TH}') and from the fourth signal detectors **74'** ($V_{OUTCOMP}'$) to evaluate passage from the step of charging of the inductor **22***b* to the step of supply of the capacitor **27**/load **28**, and vice versa.

[0130] The control logic **60** implements the method for control of the HV transistors **30***a*, **30***b*, **31***a* and **31***b* described previously and illustrated schematically in FIG. **11**, by a flowchart.

[0131] With reference to FIG. **11** (step **100**), the HV transistors **30***a* and **31***a* are closed. It is considered in the sequel of the description that the LV transistors **30***b* and **31***b* will always be in the closed state (situation of FIG. **3**B).

[0132] In this way, the inductor **22***b* is charged via the current $I_L=I_{ON}$ that flows through the HV transistors **30***a* and **31***a*.

[0133] The value of current $I_L=I_{ON}$ is monitored (step **102**) for detecting whether it reaches (or exceeds) the required threshold value I_{TH}. At the same time, the control logic **60** monitors the time interval T_{DELAY}. In this case, the time t**0** of start of the time interval T_{DELAY} corresponds to the instant of closing of the HV transistors **30***a*, **31** *a*, according to step **100**.

[0134] In the case where the current I_L has not reached the threshold I_{TH} or the time T_{DELAY} has not elapsed (output NO from step **102**), it is necessary to wait for both of these conditions for being satisfied and the control logic **60** maintain the system **20** in the states **100**, **102** until the condition $I_L \geq I_{TH}$ is satisfied. Otherwise (output YES from step **102**), control passes to the next step **104**.

[0135] In step **104** a check is made to verify whether the input voltage V_{IN} has positive or negative polarity. This operation may be performed by the comparator **86**, which receives the signal V_{IN}^+ at input.

[0136] As has already been said, a circuit equivalent to what is illustrated in FIG. **8** is coupled (in a way not illustrated in the figure) to the HV transistor **31***a*, and used in a similar way for receiving the signal with negative polarity V_{IN}^-.

[0137] In the case where the input voltage V_{IN} has a positive polarity, control passes to step **106** (output YES from step **104**), where the HV transistor **30***a* is opened, thus supplying the capacitor **27**/load **28** via the diode **36**.

[0138] In the case where the input voltage V_{IN} has a negative polarity, control passes instead to step **108** (output NO from step **104**), where the capacitor **27**/load **28** is supplied via the diode **38**.

[0139] From steps **106** and **108** control passes to step **110**, where the control logic **60** monitors just one between the signals $V_{OUTCOMP}$ and $V_{OUTCOMP}'$ (from the second current detector **74** and, respectively, fourth current detector **74'**, according to the polarity of the input signal) to detect whether the current I_{OUT} assumes a value equal to I_{OFF}. As long as $I_{OUT}>I_{OFF}$, the control logic **60** keeps the system **20** in the step of charging of the capacitor **27**/supply of the load **28**. When $I_{OUT}\leq I_{OFF}$, control returns to step **100**. Steps **100-104** are carried out, as described with reference to FIGS. **5***a*-**5***c*, in a time interval equal to at least T_{DELAY} until the current in the inductor reaches the threshold I_{TH}, whereas steps **106-110** are carried out in a time interval equal to T_{CHARGE}.

[0140] The control logic **60** is, for example, a microcontroller, or finite-state machine, configured to drive the HV transistors **30***a* and **31***a* in order to execute the steps of the method of FIG. **11**. In particular, the control logic is integrated in the same device that forms the energy harvesting interface according to the present invention (i.e., it is not an external component).

[0141] According to an embodiment alternative to the one illustrated in FIGS. **3**A and **3**B, the diodes **36** and **38** may be replaced by a respective N-channel MOSFET, or by any active component appropriately controlled for implementing the steps described. This embodiment is illustrated in FIG. **12** (energy harvesting system **20'**). These transistors are designated by the reference numbers **36'** and **38'**, respectively. The transistors **36'** and **38'** are controlled in an active way, by actively driving them in conduction or inhibition. This control is carried out by the control logic **60**, possibly by interposition of respective driving blocks. More in particular, the control logic **60** turns on the transistor **36'** at positive half-waves of the input voltage V_{IN} and as it verifies that the current I_{ON} has reached the value I_p for getting energy to flow to the capacitor **27**/load **28**. Likewise, the control logic **60** turns on the transistor **38'** at negative half-waves of the input voltage V_{IN} and at as it verifies that the current I_{ON} has reached a value, in modulus, equal to I_p for getting energy to flow to the capacitor **27**/load **28**.

[0142] FIG. **13** shows, by a flowchart, a method for control of the HV transistors **30***a*, **30***b*, **31***a*, **31***b*, **36'** and **38'**.

[0143] With reference to FIG. **13** (step **120**), the HV transistors **30***a* and **31***a* are closed. The transistors **36'** and **38'** instead, are opened. It is assumed, in the sequel of the description, that the LV transistors **30***b* and **31***b* are always in the closed state. In this way, the inductor **22***b* is charged via the current $I_L=I_{ON}$ that flows through the HV transistors **30***a* and **31***a*.

[0144] The value of current $I_L=I_{ON}$ is monitored (step **122**) for detecting whether it reaches (or exceeds) the threshold value I_{TH} required. At the same time, the control logic **60** monitors the time interval T_{DELAY}. In this case, the time t_0 of start of the time interval T_{DELAY} corresponds to the instant of closing of the HV transistors **30***a*, **31** *a*, according to step **120**.

[0145] In the case where the current I_L has not reached the threshold I_{TH} or the time T_{DELAY} has not elapsed (output NO from step **122**), it is necessary to wait for both of these conditions for being satisfied, and the control logic **60** keeps the system **20** in the states **120**, **122** until the condition $I_L\geq I_{TH}$ is satisfied. Otherwise (output YES from step **122**), control passes to the next step **124**.

[0146] In step **124**, a check is made to verify whether the input voltage V_{IN} has positive or negative polarity.

[0147] In the case where the input voltage V_{IN} has a positive polarity, control passes to step **126** (output YES from step **124**), where the HV transistor **30***a* is turned off and the transistor **36'** is turned on, thus supplying the capacitor **27**/load **28** via the transistor **36'**.

[0148] In the case where the input voltage V_{IN} has a negative polarity, control passes instead to step **128** (output NO from step **124**), where the capacitor **27**/load **28** is supplied via the transistor **38'**.

[0149] From steps **126** and **128** control passes to step **130**, where the control logic **60** monitors just one between the signals $V_{OUTCOMP}$ and $V_{OUTCOMP}'$ (according to the polarity of the input signal) to detect whether the current I_{OUT} assumes a value equal to I_{OFF}. As long as $I_{OUT}>I_{OFF}$, the control logic **60** keeps the system **20** in the step of charging of the capacitor **27**/supply of the load **28**. When $I_{OUT}\leq I_{OFF}$, control returns to step **120**.

[0150] FIG. **14** shows a vehicle **200** comprising the energy harvesting system **20** of FIGS. **3**A, **3**B or the energy harvesting system **20'** of FIG. **12**. The vehicle **200** is, in particular, an automobile. It is evident, however, that the energy harvesting system **20**, **20'** may be used in any vehicle **200** or in systems or apparatuses different from a vehicle. In particular, the energy harvesting system **20**, **20'** may find application in generic systems in which it is desirable to harvest, store, and use environmental energy, in particular by conversion of mechanical energy into electrical energy.

[0151] With reference to FIG. **14**, the vehicle **200** comprises one or more transducers **22** coupled in a per se known manner to a portion of the vehicle **200** subject to mechanical stress and/or vibrations, for converting said mechanical stress and/or vibrations into electric current.

[0152] The energy harvesting system **20**, **20'** is connected to one or more electrical loads **28***a*, . . . , **28***n*, for example via interposition of a DC-DC converter. In particular, according to an application of the present invention, the electrical loads **28***a*, . . . , **28***n* comprise TPM (tyre-parameter monitoring) sensors **250** for monitoring tire parameters **202**. In this case, the TPM sensors **250** are coupled to an internal portion of the tires **202** of the vehicle **200**. Likewise, also the transducers **22** (for example, of an electromagnetic or piezoelectric type) are coupled to an internal portion of the tires **202**. The stress of the transducers **22** while the vehicle **200** is travelling causes production of an electric current/voltage signal at output from the transducer **22** by conversion of mechanical energy into electrical energy. The electrical energy thus produced is stored, as described previously, in the storage element **27** and supplied, via the DC-DC converter that may possibly be present, to the TPM sensors **250**.

[0153] According to one embodiment, the energy harvesting system **20**, **20'**, comprising one or more transducers and the TPM sensors **250**, are glued inside one or more tires **202**. The impact of the tire **202** on the ground during motion of the vehicle **200** enables production of electrical energy.

[0154] As an alternative to what is illustrated in FIG. **14**, the energy harvesting system **20**, **20'** may be set in any other portion of the vehicle **200**, and/or used for supplying an electrical load different from, or additional to, the TPM sensors **250**.

[0155] Another possible application of the energy harvesting system **20**, **20'** is generation of electrical energy by exploiting the mechanical energy produced by an individual when he is walking or running. In this case, the energy harvesting system **20**, **20'** is set inside the shoes **300** of said individual (for example, in the sole) as illustrated schematically in FIG. **15**. In systems configured for fitness purposes, where it is of particular interest to count the number of steps, it is useful to recover energy from the vibrations induced by walking or running for being able to supply, without the use of batteries, acceleration sensors and/or RFID transmitters that are able to communicate with cellphones, music-playing devices, or with any other apparatus involved in processing information regarding the steps.

[0156] From an examination of the characteristics provided according to the present disclosure the advantages that it affords emerge clearly.

[0157] In particular, the parameter K has a highly reproducible value (minimal spread) for increasing the performance, sturdiness, and efficiency of the system **20**, **20'**, minimizing the mismatch between the positive polarity and negative polarity of the signal of the transducer and preventing phenomena of reversal of the flow of current from the capacitor **27** to the input terminals **25'**, **25"** of the rectifier circuit **24**.

[0158] The scavenging efficiency is likewise high even when the amplitude of the signal V_{TRANSD} of the transducer **22** is lower than the voltage value stored in the capacitor **27**, thus overcoming a limitation of the diode-bridge rectifier architecture.

[0159] Furthermore, since in the case of a transducer **22** of an electromagnetic type the rectifier **24** exploits the inductor **22***b* of the transducer **22**, the scavenging efficiency is high even when the amplitude of the signal of the transducer is low. In this way, the limitation imposed by the diode-bridge rectifiers, which require a voltage of the transducer V_{TRANSD} higher than $2V_{TH\_D}$, where V_{TH_D} is the threshold voltage of the diodes of the rectifier, is overcome.

[0160] Using a high-voltage (HV) technology for the capacitor **27** and for the energy harvesting interface, it is possible to store high voltages, and thus high energy, in the capacitor, consequently increasing the autonomy of operation of the TPM sensors **250**.

[0161] The method described enables implementation of an active control (of the mean value and of the ripple) of the current supplied by the transducer, and enables an optimal impedance matching between the transducer **22** and the energy harvesting interface **24**. This ensures a high efficiency η_{SCAV} of the energy harvesting interface **24***b* irrespective of the speed of rotation of the tyres **202** and of the conditions of storage of the energy in the capacitor **27**.

[0162] Furthermore, as has been said, the value of the interval T_{DELAY} may be varied according to the particular application in which the rectifier **24** operates. The rectifier **24** thus finds use in systems different from the energy harvesting system **20**, **20'**, based upon electromagnetic transducers of any type.

[0163] In addition, the rectifier circuit **24** may be used with transducers of some other type, with interposition of an appropriate circuit between the transducer and the rectifier circuit configured to provide an energy accumulator similar to the inductor **22***b*.

[0164] Further, the rectifier **24** and the energy harvesting system **20**, **20'** are of a fully integrated type, and consequently require minimal installation space.

[0165] Finally, environmental-energy harvesting is obtained even when the signal of the transducer is lower than the voltage value stored on the output capacitor, which is not possible using a diode-bridge interface of a known type as illustrated in FIG. **1**. According to the present invention, the energy harvesting interface **24** is thus able to harvest energy even when the power supplied by the transducer is very low.

[0166] Finally, it is clear that modifications and variations may be made to what has been described and illustrated herein, without thereby departing from the scope of the present invention, as defined in the annexed claims.

[0167] In particular, according to one embodiment, the rectifier circuit **24** may comprise a number of transistors different from what has been described. For instance, the rectifier circuit **24** may be a half-wave rectifier, comprising just the current detectors **72** and **74** or, alternatively, just the current detectors **72'** and **74'**. Use of a half-wave rectifier may be advantageous in the case where the input signal V_{IN} is of a known type and comprises only positive (or negative) half-waves. Its use is, however, not recommended (albeit possible) in energy harvesting systems in so far as part of the input signal would be lost, at the expense of the efficiency of the system as a whole.

[0168] Furthermore, it is not always necessary for both the conditions $t>T_{DELAY}$ and $I_L>I_{TH}$ expressed with reference to the operating condition of FIG. **4**A for being satisfied. In particular, for voltage signals generated by transducers **22** of a known type, the voltage value always reaches peaks such as to enable the threshold I_{TH} for being exceeded within the time T_{DELAY}. Furthermore, an appropriate choice of T_{DELAY} always guarantees, for practical purposes, reaching of a minimum acceptable threshold I_{TH}.

[0169] In addition, there may be present a plurality of transducers **22**, indifferently all of the same type or of different types. For instance, the transducer/transducers may be chosen in the group comprising: electrochemical transducers (configured to convert chemical energy into an electrical signal), electromechanical transducers (configured to convert mechanical energy into an electrical signal), electro-acoustic transducers (configured to convert variations of acoustic pressure into an electrical signal), electromagnetic transducers (configured to convert a magnetic field into an electrical signal), photo-electric transducers (configured to convert light energy into an electrical signal), electrostatic transducers, thermoelectric transducers, piezoelectric transducers, thermo-acoustic transducers, thermomagnetic transducers, and thermo-ionic transducers.

1. An energy harvesting interface, comprising:

a first switch and a second switch coupled together in series between a first input terminal and a first output terminal;

a third switch and a fourth switch connected together in series between a second input terminal and the first output terminal;

a first charge-transfer element coupled between the first input terminal and the second output terminal;

a second charge-transfer element coupled between the second input terminal and the second output terminal; and

a first electrical-signal-detecting device coupled across the second switch and configured to detect whether an electric storage current that flows through the second switch reaches a first threshold value, said electric storage current being associated to an electrical charge stored in an input storage element;

a second electrical-signal-detecting device coupled across the fourth switch and configured to detect whether an electric supply current that flows through the fourth switch reaches a second threshold value lower than the first threshold value; and

a control logic configured to:
  close the first, second, third, and fourth switches until the electric storage current reaches the first threshold value;
  open the first switch, thus generating the electric supply current for supplying an output second storage element through the first charge-transfer element by discharging the input storage element; and
  keep the first switch open as long as the electric supply current is higher than said second threshold value.

2. The energy harvesting interface according to claim **1**, wherein the control logic is further configured to:
keep closed the first, second, third, and fourth switches for a time interval during which the input storage element stores electrical charge through the electric storage current.

3. The energy harvesting interface according to claim **1**, wherein, when the first threshold value has been reached, the first and second electrical-signal detecting devices co-operate for generating said second threshold value.

4. The energy harvesting interface according to claim **3**,
wherein the first electrical-signal-detecting device comprises:
  a first comparator coupled across the second switch for comparing the value of the electric storage current with the first threshold value; and
  a current mirror configured to generate a scaled copy, scaled by a first proportionality factor, of the electric storage current; and
wherein the second electrical-signal-detecting device comprises:
  a scaling resistor having a value of resistance that is equal to the value of resistance of the fourth switch multiplied by a second proportionality factor that is coupled between the fourth switch and an intermediate node and configured to generate, on the intermediate node, a sum voltage signal given by the sum of the voltage signal across the fourth switch, which is a function of the output current, and the voltage signal across the scaling resistor, which is a function of said scaled copy of the electric storage current; and
  a second comparator, having a first conduction terminal biased at a reference voltage of a zero value and a second conduction terminal coupled to the intermediate node, configured to generate a comparison signal identifying a condition in which the sum voltage signal has a substantially zero value.

5. The energy harvesting interface according to claim **4**, wherein the condition whereby the sum voltage signal has a substantially zero value corresponds to an output electric supply current signal that flows through the third and fourth switches equal to the peak value of the electric storage current reduced by a third proportionality factor that is equal to the first proportionality factor divided by the second proportionality factor.

6. The energy harvesting interface according to claim **5**, wherein said peak value reduced by the third proportionality factor is said second threshold value.

7. The energy harvesting interface according to claim **4**, wherein said second switch is formed by a low-voltage transistor, the current mirror comprising the second switch and a mirror transistor, which have their respective gate terminals coupled together, said second switch having a width-to-length aspect ratio W/L that is equal to the aspect ratio W/L of the mirror transistor multiplied by the first proportionality factor.

8. The energy harvesting interface according to claim **4**, wherein the scaling resistor is a low-voltage transistor having a width-to-length aspect ratio W/L that is equal to the aspect ratio W/L of the fourth switch multiplied by said second proportionality factor.

9. The energy harvesting interface according to claim **4**, wherein the transistor that forms the scaling resistor is a modular transistor having a value of the width-to-length aspect ratio W/L that may be selected according to the need, said energy harvesting interface further comprising a memory that stores information for driving said transistor that forms the scaling resistor for enabling/disabling one or more modules of the transistor that forms the scaling resistor in order to select the respective width-to-length aspect ratio W/L.

10. The energy harvesting interface according to claim **7**, wherein said mirror transistors and said second switch are modular transistors which have a respective value of the width-to-length aspect ratio W/L that may be selected according to the need, said energy harvesting interface further comprising a memory that stores information for driving said mirror transistor and said second switch for enabling/disabling one or more respective modules of the mirror transistor and of the second switch in order to select the respective width-to-length aspect ratios W/L.

11. The energy harvesting interface according to claim **4**, wherein the first proportionality factor and the second proportionality factor are chosen with a value such as to optimize the coupling efficiency to the input port of the energy harvesting interface.

12. The energy harvesting interface according to claim **1**, wherein the input port may be coupled to a transducer of an electromagnetic type including an inductor, said input storage element being the inductor of said transducer of an electromagnetic type.

13. An energy harvesting system configured to supply an electrical load, comprising:
  a transducer configured to convert energy coming from an energy source external to said system into a transduced electrical signal;
  an electrical-energy harvesting interface, configured to receive at input the transduced electrical signal and supply at output an output signal; and
  an electrical-energy storage element coupled to the output terminals of the electrical-energy harvesting interface for receiving at input the output signal, and configured to store electrical energy configured to supply the electrical load;
  wherein the electrical-energy harvesting interface comprises:
    a first switch and a second switch coupled together in series between a first input terminal and a first output terminal;
    a third switch and a fourth switch connected together in series between a second input terminal and the first output terminal;
    a first charge-transfer element coupled between the first input terminal and the second output terminal;
    a second charge-transfer element coupled between the second input terminal and the second output terminal; and

a first electrical-signal-detecting device coupled across the second switch and configured to detect whether an electric storage current that flows through the second switch reaches a first threshold value, said electric storage current being associated to an electrical charge stored in said transducer;

a second electrical-signal-detecting device coupled across the fourth switch and configured to detect whether an electric supply current that flows through the fourth switch reaches a second threshold value lower than the first threshold value; and

a control logic configured to:

close the first, second, third, and fourth switches until the electric storage current reaches the first threshold value;

open the first switch, thus generating the electric supply current for supplying the electrical-energy storage element through the first charge-transfer element by discharging the transducer; and

keep the first switch open as long as the electric supply current is higher than said second threshold value.

14. The system according to claim **13**, further comprising a DC-DC converter connected between the electrical-energy storage element and the electrical load, said DC-DC converter being configured to supply the electrical load via the electrical energy stored in the electrical-energy storage element.

15. The system according to claim **13** as installed in an apparatus.

16. The system according to claim **15**, wherein the apparatus comprises one of a vehicle and an item of sports footwear.

17. A method for harvesting energy, comprising:

closing first, second, third, and fourth switches of an energy harvesting interface, wherein the first switch and the second switch are connected together in series between a first input terminal and a first output terminal, and wherein the third switch and the fourth switch are connected together in series between a second input terminal and the first output terminal;

detecting electric storage current that flows through the closed second switch;

keeping the first, second, third and fourth switches closed until the detected electric storage current reaches a first threshold value, said electric storage current being associated to electrical charge stored in an input storage element;

opening the first switch thus generating an electric supply current for supplying an output storage element through a first charge-transfer element by discharging the input storage element;

detecting the electric supply current that flows through the closed fourth switch;

keeping the first switch open as long as the electric supply current is higher than a second threshold value that is lower than the first threshold value.

18. The energy-scavenging method according to claim **17**, wherein detecting the electric supply current that flows through the closed fourth switch comprises:

comparing the electric current that flows through the second switch with the first threshold value and, in the case where said electric current through the second switch is equal to or higher than the first threshold value, then:

generating a scaled copy, reduced by a first proportionality factor, of the electric current that flows through the second switch; and

generating a multiple of said scaled copy by multiplying said scaled copy by a second proportionality factor to obtain said second threshold value.

(57) ABSTRACT

A device for brain stimulation using radio frequency harvesting is disclosed. The device includes a circuit implantable under a scalp of a patient, the circuit comprising a radio frequency harvesting power circuit and a stimulation circuit, and a plurality of electrodes coupled to the circuit, the plurality of electrodes providing brain stimulation to targeted areas of the brain. The electrodes may provide stimulation to targeted areas of the brain including deep brain stimulation for the treatment of Parkinson's disease and cortical stimulation for the treatment of stroke victims.

DEVICE FOR BRAIN STIMULATION USING RF ENERGY HARVESTING

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims priority under 35 U.S.C. 119(e) from provisional patent application Ser. No. 60/606,853, entitled "Device For Deep Brain Stimulation (DBS) Using RF Energy Harvesting", filed on Sep. 2, 2004, the disclosure of which is herein incorporated by reference in its entirety.

FIELD OF THE INVENTION

[0002] The present invention relates generally to systems and apparatus for providing brain stimulation and more particularly to a device for harvesting radio frequency (RF) energy that can be implanted under a human scalp to produce stimulation in different regions of the brain, including deep brain stimulation (DBS).

BACKGROUND OF THE INVENTION

[0003] DBS is a surgical technique first used in humans over 25 years ago. DBS has been used in a wide variety of brain targets, including the thalamus, globus pallidus and the subthalamic nucleus. Diseases that have been effectively treated with DBS include movement disorders including essential tremor [Lyons K E, Pahwa R. Deep Brain Stimulation and Essential Tremor, J Clin Neurophysiol. 2004 January-February;21(1):2-5], Parkinson's disease [Byrd D L, Marks W J Jr, Starr P A. Deep brain stimulation for advanced Parkinson's disease. AORN J. 2000 September;72(3):387-90, 393-408] and dystonia [Vidailhet M. et al., Bilateral deep-brain stimulation of the globus pallidus in primary generalized dystonia. N Engl J Med. 2005 Feb. 3;352(5):459-67]. Other indications for DBS are being explored, including chronic pain, cluster headache, persistent vegatative state, epilepsy, Alzheimer's, and psychiatric disorders including obsessive-compulsive disorder and intractable depression.

[0004] Parkinson's disease (PD) is an idiopathic neurodegenerative disorder that is characterized by the presence of tremor, rigidity, akinesia or bradykinesia (slowness of movement) and postural instability. It is believed to be caused by the loss of a specific, localized population of neurons in a region of the brain called the substantia nigra. These cells normally produce dopamine, a neurotransmitter that allows brain cells to communicate with each other. These dopaminergic cells in the substantia nigra are part of an elaborate motor circuit in the brain that runs through a series of discrete brain nuclei known as the basal ganglia that control movement. It is believed that the symptoms of PD are caused by an imbalance of motor information flow through the basal ganglia.

[0005] Conventionally, a medication known as levodopa has been the mainstay of treatment for patients with Parkinson's disease. However, long-term therapy with levodopa has several well-known complications that limit the medications effectiveness and tolerability. The first of these is the development of involuntary movements known as dyskinesias. These movements can be violent at times and as or more disabling than the Parkinson's symptoms themselves. The other frequent complication is the development of "on-off" fluctuations, where patients cycle between periods of good function (the "on" period) and periods of poor function (the "off" period). These fluctuations can become very frequent, up to 7 or more cycles per day, and can cause patients to become suddenly and unpredictably "off" to the point where they cannot move.

[0006] Lesioning procedures such as pallidotomy were known to improve the motor symptoms of Parkinson's disease, presumably by disruption of the abnormal neuronal activity in the motor circuitry of the basal ganglia. The discovery that MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) produced a Parkinsonian-like state in non-human primates allowed electrophysiologic study of this phenomenon by numerous investigators. The discovery that high frequency stimulation could mimic the effect of lesioning led to the use of DBS for PD in humans in the early 1990's. DBS was found to improve all of the cardinal symptoms of Parkinson's disease while allowing the patient to decrease or sometimes even eliminate the amount of levodopa medication, therefore decreasing both dyskinesia and "on-off" fluctuations.

[0007] DBS is currently the surgical treatment of choice for medically refractory Parkinson's disease. Two brain targets have been found to provide clinical benefit when chronically stimulated; the subthalamic nucleus (STN) and the internal segment of the globus pallidus (GPi). In a recent prospective, double-blinded cross-over study involving 96 patients with STN DBS and 38 patients with GPi DBS, the STN group reported an improvement in the percentage of time spent during the day with good mobility and without dyskinesia from 27% to 74%. The GPi group also reported a significant improvement, from 28% to 64%.

[0008] Although the mechanism of action is not fully understood it is thought to act by either depolarization blockade, synaptic inhibition, synaptic depression, or stimulation-induced modulation of pathologic network activity [McIntyre C C, Savasta M, Walter B L, Vitek J L. How does deep brain stimulation work? Present understanding and future questions. J Clin Neurophysiol. 2004 January-February;21(1):40-50]. It is believed that DBS acts somehow to suppress the neuronal activity by the stimulation of the region of the brain immediately adjacent to the electrode. This hypothesis seems to be supported by the fact that lesioning a specific structure in the brain has the same clinical effect as stimulating that same structure at high (greater than 100-150 Hz) frequency. In fact, DBS has largely replaced the older lesioning procedures (such as pallidotomy and thalamotomy) that used to be the mainstay of surgical treatment for movement disorders such as Parkinson's disease. The high frequency stimulation may act to hyperpolarize immediately adjacent neurons such that they become incapable of producing normal action potentials. An alternative hypothesis is that DBS may be altering more distant structures or even fibers from far removed nerve cells that are passing through or near the area of stimulation. Whatever the mechanism of action, DBS has a distinct advantage over the older lesioning techniques because it is an adjustable therapy and does not involve destruction of the patient's brain tissue.

[0009] Prior art DBS devices have several limitations that can lead to adverse effects including infection, cutaneous erosion, and lead breaking or disconnection [Temel Y,

Ackermans L, Celik H, Spincemaille G H, Van Der Linden C, Walenkamp G H, Van De Kar T, Visser-Vandewalle V. Management of hardware infections following deep brain stimulation. Acta Neurochir (Wien) 2004;146(4):355-61; Putzke J D, Wharen R E, Jr., Wszolek Z K, Turk M F, Strongosky A J, Uitti R J. Thalamic deep brain stimulation for tremor-predominant Parkinson's disease. Parkinsonism Relat Disord 2003;10(2):81-8.; Umemura A, Jaggi J L, Hurtig H I, Siderowf A D, Colcher A, Stern M B, Baltuch G H. Deep brain stimulation for movement disorders: morbidity and mortality in 109 patients. J Neurosurg 2003;98(4):779-84; Hariz M I. Complications of deep brain stimulation surgery. Mov Disord 2002;17(Suppl 3):S162-**6**]. One study found that 27% of 66 patients with implanted DBS devices had hardware problems [Kondziolka D, Whiting D, Germanwala A, Oh M. Hardware-related complications after placement of thalamic deep brain stimulator systems. Stereotact Funct Neurosurg 2002;79(3-4):228-33. This relatively high incidence of hardware problems is similar to the results of a study where 20 (25.3%) of 79 patients who received 124 permanent DBS electrode implants had 26 hardware-related complications [Oh M Y, Abosch A, Kim S H, Lang A E, Lozano A M. Long-term hardware-related complications of deep brain stimulation. Neurosurgery 2002;50(6):1268-74; discussion 1274-**6**]. In addition, intracranial electrode implantation can induce a hematoma or contusion. Nonetheless, most authors agree that the benefit to risk ratio of DBS is favorable.

[0010] A prior art DBS device is shown in **FIG. 1** and includes an electrode **100** disposed in a targeted area of the brain. The electrode is coupled to a lead **110** held in place at the top of the skull by a securement device **120**. The lead **110** is coupled to a neurostimulator **130** powered by a battery-powered pulse generator **140** by means of a lead **150**. The lead **150**, which averages about 15 inches in length, is implanted under the scalp and traverses the length of the patient's neck to the chest where the neurostimulator **130** and battery **140** are implanted.

[0011] The pulse generator **140** is typically placed underneath the skin just below the collar bone and is capable of stimulating at one or any combination of the four contacts present on the end of the electrode **110** in the brain. The parameters of the stimulating current (voltage, frequency, pulse width) can also be selected by the treating physician or health care worker. The pulse generator **140** is programmed through the skin via a telemetry device that allows the practitioner to select the desired stimulation parameters and also perform diagnostic tests on the device.

[0012] Implantation of the conventional DBS device is costly as for implantation of a single electrode in the brain for treatment of one side of the body the procedure requires three incisions; one on the top of the head, one behind the ear and the third just below the collarbone where the leads are connected. The implantation of the electrode **110** and the implantable pulse generator **140** is sometimes performed on different days. The incisions can be prone to infection in the immediate postoperative period. In some elderly patients with thin skin, the pulse generator **140** or wire can erode through the skin and become exposed to potential contamination. Infection or erosion often results in the need to remove the entire device, as antibiotic treatment alone in this setting rarely will clear the infection adequately. The lead **150** restricts the patient's mobility in the neck region and may break. Furthermore, the battery **140** must be replaced every three to five years. Additional drawbacks of the DBS device include the risk of erosion of the leads or hardware, infection, and magnetic sensitivity.

[0013] A prior art deep brain stimulation system is disclosed in U.S. Pat. No. 6,920,359 entitled "Deep Brian Stimulation System for the Treatment of Parkinson's Disease or Other Disorders". The DBS system includes a small, implantable pulse generator implanted directly in the cranium of the patient, thereby eliminating the long lead wires conventionally used. The disclosed system does not provide for the harvesting of energy to power the pulse generator.

[0014] As noted in Table 1, there are several current and potential indications for deep brain stimulation.

[0015] Known systems for providing electrical stimulus to the motor cortex of the brain, such as the Northstar Stroke Recovery Treatment System available from Northstar Neuroscience, Inc., also include an implantable pulse generator implanted in the pectoral area of a patient. A cortical stimulation lead includes an electrode connected to the implantable pulse generator which is used to deliver stimulation to the cortex. The electrode is placed on top of the dura and coupled to the implantable pulse generator by means of a lead which traverses the length of the patient's neck to the patient's pectoral area.

[0016] Motor cortex stimulation (MCS) is a process involving the application of stimulation signals to the motor cortex in the brain of a patient during physical rehabilitation of the disabled region of the body. The MCS system includes a pulse generator connected to a strip electrode that is surgically implanted over a portion of only the motor cortex (precentral gyrus). Because MCS involves the application of stimulation signals to surface regions of the brain rather than deep neural structures, electrode implantation procedures for MCS are significantly less invasive and time consuming than those for DBS. The current evaluation of MCS is for stroke. Stroke-related disabilities affect more than 200,000 people in the U.S. each year. Good results have been reported in MCS treatment of stroke victims. With a MCS device, a stamp-sized electrode is placed on the surface of the brain. This is attached to a wire that goes through the neck to an implantable pulse generator in the pectoral area.

[0017] Neurostimulation and responsive neurostimulation (RNS) are also being tested for the treatment of medically refractory epilepsy. In treating epilepsy, the RNS system can be designed to detect abnormal electrical activity in the brain and respond by delivering electrical stimulation to normalize brain activity before the patient experiences seizure symptoms. For either neurostimulation or RNS for treatment of epilepsy the electrode or electrodes of the device deliver a short train of electrical pulses to the brain near the patient's seizure focus.

[0018] In order to obviate the need for long leads and batteries, attempts have been made in the prior art to transmit energy through space from a base station to a remote station. One such system is disclosed in U.S. Pat. No. 6,289,237 entitled "Apparatus for Energizing a Remote Station and Related Method". The base station transmits energy which may be RF power, light, acoustic, magnetic or other suitable forms of space transmitted or "radiant" energy to the remote station. Within the remote station, the received

energy is converted into DC power which serves to operate the remote station. The source of power for the remote station is the base station and, therefore, there is no need for the remote station to carry an electrical storage device such as a battery. It is suggested that this facilitates the remote station being encapsulated within a suitable protective material, such as a resinous plastic. Homopolymers, elastomers and silicon dioxide are also suggested as suitable materials for such purposes. Further, it is suggested that this facilitates miniaturization of the remote station and placing the remote station in functionally desirable locations which need not be readily accessible. The remote station, for example, could be implanted in a patient.

[0019] The use of a wireless communication link between a base station and transponders in a radio frequency identification system employing modulated back-scattered waves is also known. See Rao, An Overview of Bulk Scattered Radio Frequency Identification System (RFID) IEEE (1999). It has also been suggested to employ a silicon chip in a transponder having a change pump on voltage doubler current. Hornby, RFID Solutions for the Express Parcel and Airline Baggage Industry, Texas Instruments, Limited (Oct. 7, 1999).

[0020] For use in miniaturized electronic chip systems, an electronic article containing a microchip having at least one antenna structured to communicate with an antenna remotely disposed with respect to the microchip is disclosed in U.S. Pat. No. 6,615,074 entitled "Apparatus for Energizing a Remote Station and Related Method". Power enhancement is achieved using a voltage doubler. The antenna of the disclosed apparatus is comparable in volume to a Smart Dust device. Smart Dust is a combination MEMS/Electronic device on the order of 1 mm×1 mm×1 mm.

[0021] What is needed therefore is a brain stimulation device that overcomes the disadvantages of the prior art brain stimulation devices. What is needed is a brain stimulation device that requires a single implantation site and surgery. What is also needed is a brain stimulation device that uses RF energy as a power source. What is further needed is a brain stimulation device that converts RF energy and stores the converted RF energy. What is also needed is a brain stimulation device that is flexible and implantable under the scalp. What is needed is a brain stimulation device that does not require leads or a pulse generator to be placed outside of the head area that are subject to disconnection or breakage. What is also needed is a brain stimulation device for electrical stimulation in the brain that is smaller and more self-contained and that does not require a pulse generator to be implanted elsewhere in the body. What is further needed is a device that is less susceptible to hardware problems or complications. What is needed is a device that has less potential for erosion through the skin. What is also needed is a device that is has a power source that does not need to be replaced.

SUMMARY OF INVENTION

[0022] The device for brain stimulation using RF energy harvesting of the present invention overcomes the disadvantages of the prior art, fulfills the needs in the prior art, and accomplishes its various purposes by providing a brain stimulation device that harvests radio frequency energy and is implantable under the scalp. The brain stimulation device of the invention may include an electrode that penetrates into the brain to provide neurostimulation to the brain. The brain stimulation device may also include an electrode that is used to provide stimulation to the brain cortex.

[0023] In accordance with one aspect of the invention, a device for brain stimulation using radio frequency harvesting includes a circuit implantable under a scalp of a patient, the circuit comprising a radio frequency harvesting power circuit and a stimulation circuit, and a plurality of electrodes coupled to the circuit, the plurality of electrodes providing brain stimulation to targeted areas of the brain. An advantage of this system is that it may use "trickle charging" wherein the device is charged by the harvesting power circuit. Moreover, anther advantage of this invention is the power transmitter which sends power to the device can be used both to send power and to send information.

[0024] There has been outlined, rather broadly, the more important features of the invention in order that the detailed description thereof that follows may be better understood, and in order that the present contribution to the art may be better appreciated. There are, of course, additional features of the invention that will be described below and which will form the subject matter of the claims appended herein.

[0025] In this respect, before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of design and to the arrangement of components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced and carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein, as well as the abstract, are for the purpose of description and should not be regarded as limiting.

[0026] As such, those skilled in the art will appreciate that the conception upon which this disclosure is based may readily be utilized as a basis for the designing of other methods and systems for carrying out the several purposes of the present invention. It is important, therefore, that the claims be regarded as including such equivalent methods and systems insofar as they do not depart from the spirit and scope of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0027] The accompanying drawings, which are incorporated in and form a part of the specification, illustrate the embodiments of the present invention and together with the description, serve to explain the principles of the invention. In the drawings:

[0028] **FIG. 1** is a schematic representation of a prior art DBS device;

[0029] **FIG. 2A** is a schematic representation of a device for deep brain stimulation using RF energy harvesting in accordance with the invention;

[0030] **FIG. 2B** is a schematic representation of a device for cortical stimulation using RF energy harvesting in accordance with the invention;

[0031] **FIG. 2C** is a schematic representation of the device of **FIG. 2A** illustrating lead securement devices;

[0032] **FIG. 2D** is a schematic representation of the device of **FIG. 2A** illustrating an attachment means for connecting a lead wire to a circuit of the device;

[0033] **FIG. 3** is a schematic representation of a stimulation circuit in accordance with the invention;

[0034] **FIG. 4** is a graph showing an output enable pulse from a microcontroller of the stimulation circuit shown in **FIG. 3** in accordance with the invention;

[0035] **FIG. 5** is a graph showing an output signal from the microcontroller of the stimulation circuit shown in **FIG. 3** applied across a resistive load in accordance with the invention.

[0036] **FIG. 6** is a graph showing pulses across the resistive load;

[0037] **FIG. 7** is a schematic representation of an external programming circuit in accordance with the invention;

[0038] **FIG. 8A** is a schematic representation of an external power circuit inductively coupled to a power circuit in accordance with the invention;

[0039] **FIG. 8B** is a schematic representation of an alternative embodiment of the external power circuit non-inductively coupled to the power circuit in accordance with the invention;

[0040] **FIG. 9** is an illustration of a PCB layout of the stimulating circuit in accordance with the invention;

[0041] **FIG. 10** is an illustration of the external power circuit in accordance with the invention/

[0042] **FIG. 11** is an oscilloscope screen showing the output voltage from an oscillator of the external power circuit in accordance with the invention;

[0043] **FIG. 12** is an oscilloscope screen showing a voltage across a primary coil series resistance of the external power circuit in accordance with the invention;

[0044] **FIG. 13** is a graph showing the effect of skin disposed between the primary coil and a secondary coil of the stimulating circuit in accordance with the invention;

[0045] **FIG. 14** is a graph showing the effect of freezing the thawing the skin in accordance with the invention;

[0046] **FIG. 15** is a graph of the output voltage over time in accordance with the invention; and

[0047] **FIG. 16** is a pictoral representation of a model having the stimulation circuit implanted in a scalp and the external powering circuit disposed in a hat in accordance with the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0048] A device for deep brain stimulation using RF energy harvesting **200** of he invention is shown implanted under a human scalp in **FIG. 2A**. A flexible, implantable disc-shaped portion **210** having a diameter of about 6 cm and a thickness of between 3 and 4 mm may be formed of a biocompatible material and include circuitry as further described herein. Lead wires **220** may lead from the circuitry and be coupled to electrodes **230** disposed in targeted areas of the brain. Electrodes **230** may include conventional electrodes used for DBS. Neurostimulation lead securement devices **240** including burr hole caps may serve to secure the lead wires **220** to the electrodes. The circuitry may be operable to harvest and store RF energy, control the operation of the device **200** and provide neurostimulation pulses and signals to the targeted areas of the brain.

[0049] A device for cortical brain stimulation using RF energy harvesting **250** of the invention is shown in **FIG. 2B**. The flexible, implantable disc-shaped portion **210** is shown implanted under the scalp. Lead wires **270** may lead from the circuitry of the disc-shaped portion **260** and be coupled to electrodes **280** disposed on the cortical dura.

[0050] With reference to **FIGS. 2C and 2D**, lead securement devices **240** are shown. Lead securement devices **240** may include StimLoc devices available from ign. Lead securement devices **240** may minimize dislodgment of lead wires **220**.

[0051] Lead wires **220** may be coupled to the circuitry of the disc-shaped portion **210** by means of connectors **215**. Connectors **215** may include a plurality of male contacts **217** for providing electrical contact to corresponding female contacts of the circuitry (not shown). A screw hole **219** may be formed in the connector **215** for securing the connectors **215** to the disc-shaped portion **210** and for securing the disc-shaped portion **210** to the skull of the patient.

[0052] The circuitry may include a stimulation circuit **300** as shown in **FIG. 3** and a portion of the power circuit as shown in **FIG. 8A**. The stimulation circuit **300** may include a circuit printed onto the disc-shaped portion **210**. For purposes of illustration, the stimulation circuit **300** may be modeled using discreet components. The stimulation circuit **300** may include a PIC microcontroller **310** such as the PIC16LF87. The microcontroller **310** may manage the internal stimulation circuitry. A low frequency receiver chip **320** such as the ATA5283 may be coupled to the microcontroller **310** and may convert RF communications into programming commands which the microcontroller **310** interprets. An array of analog switches **330** such as the MAX4066 may be coupled to the microcontroller **310** and connect to voltage dividers **340** to output stimulation locations. Analog switches **330** may be coupled to electrodes **230** (**FIG. 2A**) and **260** (**FIG. 2B**).

[0053] According to internal parameters which can be modified via an external RF programming signal, the microcontroller **310** may control analog switch states to determine a voltage applied to any combination of four output locations including four output locations on electrodes **230** and **260**. The maximum possible voltage is determined by the supply voltage to the circuit **300**. A pulsing frequency, nominally 185 Hz, can be adjusted slightly as well as whether a stimulation pulse is applied or not. In order to conserve energy, the microcontroller **310** may enter a standby mode for 4 ms between pulses, greatly reducing power consumption. The microcontroller **310** may be operated with an internal clock frequency of 125 KHz, giving an efficient tradeoff between power conservation and proper functionality. This clock frequency allows pulse durations in increments of 32 micro-seconds. The output pulse duration can be adjusted between ~60 and ~180 microseconds. With reference to **FIG. 4**, **FIG. 5** and **FIG. 6**, the frequency output, varied voltage output and pulse duration of the microcontroller **310** are shown respectively.

[0054] Every pulsing cycle, the programming input from the low frequency receiver chip **320** may be checked. If a programming signal is present, an input code may be read

sequentially and the specified parameter adjusted to a new value, after which the program continues its pulsing routine.

[**0055**] The low frequency receiver chip **320** used for receiving external programming commands uses an amplitude shift keying (ASK) protocol. The state of a 125 KHz signal being received determines the output voltage of the low frequency receiver chip **320**: on-high, off-low. While waiting for a signal, the low frequency receiver chip **320** may remain in standby mode, conserving power. Upon the presence of a programming signal, the low frequency receiver chip **320** may wake up and send the coded data to the microcontroller **310**, after which the microcontroller **310** may tell the low frequency receiver chip **320** to enter standby mode again. The programming signal may include a preliminary "on" time to wake up the low frequency receiver chip **320**, a 4-bit header, a 3-bit parameter identifier, and a 4-bit data value. Each bit time is 2 milliseconds, allowing enough time for the microcontroller **310** to process the bit reception before the next bit arrives. An antenna attached to a coil input of the low frequency receiver chip **320** may be a short wire having a strong programming signal.

[**0056**] Eight analog switches **330** may be used to control the output pulsing. Four switches **330** may determine a path of the selected voltage to the four possible output locations. Each of these may be controlled by one of the microcontroller outputs, which are in turn enabled or disabled depending on the internal variable for output locations. The inputs of the four switches **330** may be attached to the outputs of the other four switches **330**. The inputs of these four switches **330** may all be attached to different voltage dividers **340**, providing four different voltage levels, ranging from three quarters of the supply voltage to the supply voltage maximum of 3V. Each switch **330** may be controlled by an individual microcontroller signal, which also drives the voltage divider **340** for its particular switch **330**. For every pulse, only one of these four microcontroller signals is active, enabling the voltage from its divider **340** to be sent to the output switches **330** and ultimately to the electrodes **230** and **260**. The use of static voltage dividers **340** to provide output voltage scaling may minimize power consumption. In an alternative embodiment of the invention, a custom digital-analog converter could be used to allow for a higher range of stimulation voltages.

[**0057**] When tested for power consumption, a ~1 Ω resistor was put in series with a powering circuitry described herein. The voltage measured across the resistor while in operation was approximately 17 μV, implying that the DC current required is ~17 μA. At a supply voltage of 3 V, this equates to a power consumption of 51 μW. If operated for 24 hours, the implant would consume a little over 4.4 Joules/day. Typical parameters of a stimulation signal provided for Parkinson's disease are a series of pulses of 120 microsecond duration, 2.5 volts in strength at a repetition rate of 185 pulses per second. Assuming these typical parameters, there are:

185 pulses/second*60 seconds/minute*60 minutes/hour*24 hours/day=1.5984*10^7 pulses/day.

With pulse duration of 120 micro seconds, this gives a total energy application duration of 1.5984*10^7*120*$10^{6=1918.08}$ seconds. With 2.5 volts and 50 micro amps=120 micro watts, the total energy required for stimulation is 120*10^6 watts*1918.08 seconds=0.2302 joules per day. As disclosed herein, energy harvesting by the power circuit is on the order of 12-15 joules per day and the stimulation energy required is more than adequately provided by the power circuit.

[**0058**] An external programmer circuit **700** may include a microcontroller **710** including a PIC16LF87, an inductor/capacitor (LC) oscillating circuit **720** (125 KHz), and an intermediate MOSFET driver **730** including a TC4422 as shown in **FIG. 7**. The MOSFET driver **730** may supply enough energy for driving the LC circuit **720**. When a programming signal is to be sent, a button (not shown) may be pressed, telling the microcontroller **710** to read its inputs and stimulate the MOSFET driver **730** to oscillate the LC circuit **720** according to a communication protocol. Input voltages may be controlled by simple switches. Four switches may dictate the value to be sent, while five switches may dictate which parameter is to be changed. Only one of these switches should be on at one time. A Phidget RFID antenna **740** designed for 125 KHz may be attached to the high voltage side of a capacitor **750** of the LC circuit **720** for sending the programming signal. The circuit **700** may be powered via a 12-Volt wall supply. The 12 V drives the MOSFET driver **730** and is regulated to 5 V for the switches and microcontroller **710**.

[**0059**] An external powering circuit **800** may include a battery **810** for powering an oscillator **820** which drives a transformer-like setup **830** as shown in **FIG. 8A**. The coils **835** on one side of the transformer **830** may be disposed in a cap worn on the head of a patient, a headband worn on the head of the patient, or on a headboard of a bed in which the patient lies. The coils **840** on the other side of the transformer **830** may be coupled to the stimulation circuit **300** and may be disposed proximate the coils **835**. An AC signal coming from coil **840** may be amplified and rectified through a charge pump **850** having three stages, after which a voltage may be clamped with a regulator **860** to prevent spiking. A control circuit **870** may control operation of the voltage regulator **860**.

[**0060**] The oscillator **820** may include an LTC6900. This oscillator **820** produces a 50% duty cycle square wave to drive the primary coil **835** of the transformer **830** and requires only a potentiometer for adjusting the frequency. The charge pump **850** may be a Cockroft Walton voltage multiplier, utilizing a ladder of diodes and capacitors to rectify and amplify the signal. The amplification depends on the number of stages used. Three stages have been found to be enough for a substantial voltage multiplication across a load of 200 KΩ. The capacitors may be 0.1-μF each and the diodes may include BAT54SW surface mount diodes with a forward voltage drop of ~0.24-V. The regulator **860** may include an LT1521-3, which clamps a higher input voltage to 3 V.

[**0061**] Previous empirical testing showed square coils (both primary **835** and secondary **840**), 1 in.×1 in., with 5 turns each are effective for transferring enough energy to power the stimulation circuit **300**. Coils **840** are shown in PCB layout in **FIG. 9** and coils **835** are shown in PCB layout in **FIG. 10**.

[**0062**] The optimal frequency depends on the dielectric and distance between coils **835** and **840**. Frequencies in the range of 2 MHz to 15 MHz may be used. The oscillator **820** can be powered with 3 AAA batteries (4.5 V). In examining

the actual signal through the primary coil **835**, the voltage waveforms in **FIG. 11** and **FIG. 12** were obtained. **FIG. 11** shows the output voltage from the oscillator **820**. **FIG. 12** shows the voltage across the primary coil series resistance, from which the RMS current is calculated to be 29.36 mA_{RMS}.

[**0063**] The embodiment described above provides for near field harvesting and includes inductive coupling between coils **835** and **840**. With reference to **FIG. 8B** and in an alternative embodiment of the invention, the power circuit **865** for powering the stimulation circuit **300** may be non-inductively coupled to an external source of RF energy **880**. In this far field embodiment, the power circuit **865** may be disposed in a wrist band worn by the patient, in a room transmitter or in a transmitter disposed in a building occupied by the patient. In yet another alternative embodiment of the invention, the power circuit **865** may harvest ambient RF energy such as energy transmitted in space by using an inherently tuned antenna as described in U.S. Pat. No. 6,856,291, the description of which is incorporated by reference in its entirety herein. Furthermore, a rechargeable battery or other storage device (not shown) may be employed to store harvested energy. "Non-inductive" as described herein being directed RF.

[**0064**] To demonstrate the effectiveness of the powering and programming schemes through tissue, the device **200** was tested through swine skin. Clear tape was used to cover the conductive surfaces on the primary coil **835** and the secondary coil **840** to prevent interaction with the moisture on the skin. This tape had negligible effect on the inductive coupling.

[**0065**] Three different tests were performed, each following the same procedure. At a certain separation, the voltage powering the primary coil oscillator **820** was adjusted and the maximum output voltage from the secondary coil voltage regulator **860** was measured. The primary coil oscillator voltage started at 5 V and was decreased in increments of 0.1 V until the maximum regulator output voltage had reached a steady minimum.

[**0066**] The first test was performed with no skin between the transformer coils **835** and **840**. Data was acquired at separations of 5 mm, 7 mm, and 10 mm, values chosen based on the common range of human scalp thickness. The second test used fresh swine skin of thicknesses 5 mm and 7 mm between the transformer coils **835** and **840**. The test was interrupted, preventing the testing of 10 mm thick skin. The third test used the same pieces of swine skin, 5, 7, and 10 mm thick, after they had been frozen and thawed.

[**0067**] **FIG. 13** shows the results from the first two tests for comparison purposes. The presence of the skin reduced the inductive coupling between the coils, and hence the possible maximum output voltage in the range of 1.5-3.8 V. At 4.0 V and above, the maximum output voltage of ~3 V is obtainable even with the presence of the skin.

[**0068**] The same pieces of skin were tested a second time due to interruption of the first test. However, they had all been frozen and thawed in the interim, affecting the results slightly. **FIG. 14** shows the effect that the freezing and thawing of the skin had on the energy transfer of the transformer coils. Both the 7- and 10-mm thick pieces of skin reduced the inductive coupling, but the 5-mm skin actually improved in performance. This may be due to the presence of a layer of fat in both the 7- and 10-mm pieces that is absent in the 5-mm piece.

[**0069**] Another test was performed to find the effect of the skin over time. The stimulus for this test was the degrading performance of the 10-mm thick skin over time during the interrupted test mentioned above. For this test, the 7-mm thick piece of skin was used between the primary and secondary coil. The frequency was adjusted to produce a maximum output voltage, which was measured successively over a period of time. The results shown in **FIG. 15** support the fact that performance does not degrade over time. The slight drop in output voltage is likely due to the mechanical nature of the frequency-tuning potentiometer. Notice that the output voltage reaches a steady value and remains constant after that point.

[**0070**] In order to demonstrate the concept and functionality of the device **200**, a model **1600** was created as shown in **FIG. 16**. The stimulation circuit **300** was put on top of a Styrofoam head **1610** with wires running down through the bottom for power- and pulse-monitoring purposes. An ABS Plastic cap (not shown) was made to simulate the head's scalp, covering the stimulation circuit **300**. The primary powering coil **835** with the batteries **810** was secured in a hat **1620** over the position of the stimulation circuit **300** to provide for near field inductive coupling.

[**0071**] The device **200** was tested on a cadaver head to show that a signal may be generated through the scalp and to demonstrate the programmability of the device **200** during stimulation. First, an incision was made in the scalp of the cadaver head. The secondary coil **840** was inserted and placed on the skull and the incision was sewn, leaving the lead wires **220** of the circuit exposed. Six wires were used on the implanted circuitry, four representing the electrodes **230**, which were connected to an oscilloscope and two wires for power and ground. The primary coil **835** was then taped on the scalp directly on top of the implanted circuitry and connected to a power supply.

[**0072**] The experiment began by demonstrating the programmability of the stimulation circuit **300**. Four parameters were varied and displayed on the oscilloscope; pulse width (60, 120 and 180 micro seconds), amplitude (2.34V, 2.75V, 2.94V, 3.13 V), frequency (191 and 194 Hz) and the shifting from one stimulating probe to another (i.e. probe **1** to probe **2** or probe **1** to all four probes). A 10K OHM resistor was used to represent the brain resistance, however this resistance is higher than the resistance for the brain (900 to 1100 Ohms), but a 10 k Ohm resistor was used to ensure there was enough power.

[**0073**] Next, several voltages were tested to determine the output source voltage of the power circuit **865**. Initially, the power supply connected to the primary coil **835** was set at 5 V and was decremented by 0.1 V to 1.2 V. The voltage on the secondary coil **840** was clamped so as not to exceed 3V. As the voltage decreased on the power supply, the output voltage on the secondary coil **840** was steady at 3 V until it declined around 2.2 V. Once the voltage decreased from 3V, a potentiometer was adjusted to obtain the maximum voltage. The data obtained shows the when the voltage drops, the amplitude voltage and frequency drop off as well.

[**0074**] The device for brain stimulation using RF harvesting of the present invention provides a brain stimulation device that requires a single implantation site and surgery to thereby reduce both the cost and trauma to the patient of the implantation procedure. The brain stimulation device further uses RF energy as a power source to eliminate the need for a battery implanted in the pectoral area of the patient. The brain stimulation device further converts RF energy and

stores the converted RF energy for use in stimulation of targeted brain areas. The brain stimulation device is flexible and implantable under the scalp to minimize discomfort for the patient.

[0075] The foregoing description of the embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above teaching. It is intended that the scope of the invention be limited not by this detailed description, but rather by the claims appended hereto.

We claim:

1. A system for brain stimulation using radio frequency harvesting comprising:

a device implantable under a scalp of a patient, the device comprising a radio frequency harvesting power circuit and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

2. The system of claim 1, wherein the device is fabricated from a biocompatible substrate.

3. The system of claim 1, wherein the device is flexible and conformable to a shape of the scalp.

4. The system of claim 1, wherein the power circuit comprises a charge pump inductively coupled to a primary coil of an external power circuit.

5. The system of claim 1, wherein the power circuit comprises an inherently tuned antenna for harvesting energy transmitted in space.

6. The system of claim 1, wherein the at least one electrode provides deep brain stimulation.

7. The system of claim 1, wherein the at least one electrode provides cortical stimulation.

8. The system of claim 1, further comprising a programming circuit operable to control the stimulation circuit.

9. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit voltage output.

10. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit output pulse width.

11. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit output frequency.

12. The system of claim 1, further comprising an energy storage device coupled to the device.

13. A system for brain stimulation comprising:

a device implantable under a scalp of a patient, the device comprising a coupled power circuit and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

14. The system of claim 13, wherein the coupled power circuit is inductively coupled.

15. The system of claim 13, wherein the coupled power circuit is non-inductively coupled.

16. A system for brain stimulation comprising:

a device implantable under a scalp of a patient, the device comprising a power circuit powered by ambient radio frequency energy and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

17. The system of claim 1, wherein the at least one electrode provides brain stimulation to targeted areas of the brain in response to signals received from the stimulation circuit.

18. A method of providing brain stimulation, comprising:

harvesting power in a power harvesting circuit in a device implantable under the scalp of a patient; and

providing brain stimulation to targeted areas of the brain with at least one electrode connected to the power harvesting circuit.

19. The method of claim 18, wherein the power harvesting circuit harvests radio frequency energy.

20. The method of claim 18, wherein the power harvesting circuit harvests energy by an inductively coupled power circuit in the device.

21. The method of claim 18, wherein the power harvesting circuit harvests energy by a non-inductively coupled power circuit in the device.

22. The method of claim 18, wherein the brain stimulation is used to treat Parkinson's disease.

23. The method of claim 18, wherein the brain stimulation is used to treat stroke patients.

(57) **ABSTRACT**

A device for brain stimulation using radio frequency harvesting is disclosed. The device includes a circuit implantable under a scalp of a patient, the circuit comprising a radio frequency harvesting power circuit and a stimulation circuit, and a plurality of electrodes coupled to the circuit, the plurality of electrodes providing brain stimulation to targeted areas of the brain. The electrodes may provide stimulation to targeted areas of the brain including deep brain stimulation for the treatment of Parkinson's disease and cortical stimulation for the treatment of stroke victims.

DEVICE FOR BRAIN STIMULATION USING RF ENERGY HARVESTING

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims priority under 35 U.S.C. 119(e) from provisional patent application Ser. No. 60/606,853, entitled "Device For Deep Brain Stimulation (DBS) Using RF Energy Harvesting", filed on Sep. 2, 2004, the disclosure of which is herein incorporated by reference in its entirety.

FIELD OF THE INVENTION

[0002] The present invention relates generally to systems and apparatus for providing brain stimulation and more particularly to a device for harvesting radio frequency (RF) energy that can be implanted under a human scalp to produce stimulation in different regions of the brain, including deep brain stimulation (DBS).

BACKGROUND OF THE INVENTION

[0003] DBS is a surgical technique first used in humans over 25 years ago. DBS has been used in a wide variety of brain targets, including the thalamus, globus pallidus and the subthalamic nucleus. Diseases that have been effectively treated with DBS include movement disorders including essential tremor [Lyons K E, Pahwa R. Deep Brain Stimulation and Essential Tremor, J Clin Neurophysiol. 2004 January-February;21(1):2-5], Parkinson's disease [Byrd D L, Marks W J Jr, Starr P A. Deep brain stimulation for advanced Parkinson's disease. AORN J. 2000 September;72(3):387-90, 393-408] and dystonia [Vidailhet M. et al., Bilateral deep-brain stimulation of the globus pallidus in primary generalized dystonia. N Engl J Med. 2005 Feb. 3;352(5):459-67]. Other indications for DBS are being explored, including chronic pain, cluster headache, persistent vegatative state, epilepsy, Alzheimer's, and psychiatric disorders including obsessive-compulsive disorder and intractable depression.

[0004] Parkinson's disease (PD) is an idiopathic neurodegenerative disorder that is characterized by the presence of tremor, rigidity, akinesia or bradykinesia (slowness of movement) and postural instability. It is believed to be caused by the loss of a specific, localized population of neurons in a region of the brain called the substantia nigra. These cells normally produce dopamine, a neurotransmitter that allows brain cells to communicate with each other. These dopaminergic cells in the substantia nigra are part of an elaborate motor circuit in the brain that runs through a series of discrete brain nuclei known as the basal ganglia that control movement. It is believed that the symptoms of PD are caused by an imbalance of motor information flow through the basal ganglia.

[0005] Conventionally, a medication known as levodopa has been the mainstay of treatment for patients with Parkinson's disease. However, long-term therapy with levodopa has several well-known complications that limit the medications effectiveness and tolerability. The first of these is the development of involuntary movements known as dyskinesias. These movements can be violent at times and as or more disabling than the Parkinson's symptoms themselves. The other frequent complication is the development of "on-off" fluctuations, where patients cycle between periods of good function (the "on" period) and periods of poor function (the "off" period). These fluctuations can become very frequent, up to 7 or more cycles per day, and can cause patients to become suddenly and unpredictably "off" to the point where they cannot move.

[0006] Lesioning procedures such as pallidotomy were known to improve the motor symptoms of Parkinson's disease, presumably by disruption of the abnormal neuronal activity in the motor circuitry of the basal ganglia. The discovery that MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) produced a Parkinsonian-like state in non-human primates allowed electrophysiologic study of this phenomenon by numerous investigators. The discovery that high frequency stimulation could mimic the effect of lesioning led to the use of DBS for PD in humans in the early 1990's. DBS was found to improve all of the cardinal symptoms of Parkinson's disease while allowing the patient to decrease or sometimes even eliminate the amount of levodopa medication, therefore decreasing both dyskinesia and "on-off" fluctuations.

[0007] DBS is currently the surgical treatment of choice for medically refractory Parkinson's disease. Two brain targets have been found to provide clinical benefit when chronically stimulated; the subthalamic nucleus (STN) and the internal segment of the globus pallidus (GPi). In a recent prospective, double-blinded cross-over study involving 96 patients with STN DBS and 38 patients with GPi DBS, the STN group reported an improvement in the percentage of time spent during the day with good mobility and without dyskinesia from 27% to 74%. The GPi group also reported a significant improvement, from 28% to 64%.

[0008] Although the mechanism of action is not fully understood it is thought to act by either depolarization blockade, synaptic inhibition, synaptic depression, or stimulation-induced modulation of pathologic network activity [McIntyre C C, Savasta M, Walter B L, Vitek J L. How does deep brain stimulation work? Present understanding and future questions. J Clin Neurophysiol. 2004 January-February;21(1):40-50]. It is believed that DBS acts somehow to suppress the neuronal activity by the stimulation of the region of the brain immediately adjacent to the electrode. This hypothesis seems to be supported by the fact that lesioning a specific structure in the brain has the same clinical effect as stimulating that same structure at high (greater than 100-150 Hz) frequency. In fact, DBS has largely replaced the older lesioning procedures (such as pallidotomy and thalamotomy) that used to be the mainstay of surgical treatment for movement disorders such as Parkinson's disease. The high frequency stimulation may act to hyperpolarize immediately adjacent neurons such that they become incapable of producing normal action potentials. An alternative hypothesis is that DBS may be altering more distant structures or even fibers from far removed nerve cells that are passing through or near the area of stimulation. Whatever the mechanism of action, DBS has a distinct advantage over the older lesioning techniques because it is an adjustable therapy and does not involve destruction of the patient's brain tissue.

[0009] Prior art DBS devices have several limitations that can lead to adverse effects including infection, cutaneous erosion, and lead breaking or disconnection [Temel Y,

Ackermans L, Celik H, Spincemaille G H, Van Der Linden C, Walenkamp G H, Van De Kar T, Visser-Vandewalle V. Management of hardware infections following deep brain stimulation. Acta Neurochir (Wien) 2004;146(4):355-61; Putzke J D, Wharen R E, Jr., Wszolek Z K, Turk M F, Strongosky A J, Uitti R J. Thalamic deep brain stimulation for tremor-predominant Parkinson's disease. Parkinsonism Relat Disord 2003;10(2):81-8.; Umemura A, Jaggi J L, Hurtig H I, Siderowf A D, Colcher A, Stern M B, Baltuch G H. Deep brain stimulation for movement disorders: morbidity and mortality in 109 patients. J Neurosurg 2003;98(4):779-84; Hariz M I. Complications of deep brain stimulation surgery. Mov Disord 2002;17(Suppl 3):S162-**6**]. One study found that 27% of 66 patients with implanted DBS devices had hardware problems [Kondziolka D, Whiting D, Germanwala A, Oh M. Hardware-related complications after placement of thalamic deep brain stimulator systems. Stereotact Funct Neurosurg 2002;79(3-4):228-33. This relatively high incidence of hardware problems is similar to the results of a study where 20 (25.3%) of 79 patients who received 124 permanent DBS electrode implants had 26 hardware-related complications [Oh M Y, Abosch A, Kim S H, Lang A E, Lozano A M. Long-term hardware-related complications of deep brain stimulation. Neurosurgery 2002;50(6):1268-74; discussion 1274-**6**]. In addition, intracranial electrode implantation can induce a hematoma or contusion. Nonetheless, most authors agree that the benefit to risk ratio of DBS is favorable.

[0010] A prior art DBS device is shown in **FIG. 1** and includes an electrode **100** disposed in a targeted area of the brain. The electrode is coupled to a lead **110** held in place at the top of the skull by a securement device **120**. The lead **110** is coupled to a neurostimulator **130** powered by a battery-powered pulse generator **140** by means of a lead **150**. The lead **150**, which averages about 15 inches in length, is implanted under the scalp and traverses the length of the patient's neck to the chest where the neurostimulator **130** and battery **140** are implanted.

[0011] The pulse generator **140** is typically placed underneath the skin just below the collar bone and is capable of stimulating at one or any combination of the four contacts present on the end of the electrode **110** in the brain. The parameters of the stimulating current (voltage, frequency, pulse width) can also be selected by the treating physician or health care worker. The pulse generator **140** is programmed through the skin via a telemetry device that allows the practitioner to select the desired stimulation parameters and also perform diagnostic tests on the device.

[0012] Implantation of the conventional DBS device is costly as for implantation of a single electrode in the brain for treatment of one side of the body the procedure requires three incisions; one on the top of the head, one behind the ear and the third just below the collarbone where the leads are connected. The implantation of the electrode **110** and the implantable pulse generator **140** is sometimes performed on different days. The incisions can be prone to infection in the immediate postoperative period. In some elderly patients with thin skin, the pulse generator **140** or wire can erode through the skin and become exposed to potential contamination. Infection or erosion often results in the need to remove the entire device, as antibiotic treatment alone in this setting rarely will clear the infection adequately. The lead **150** restricts the patient's mobility in the neck region and may break. Furthermore, the battery **140** must be replaced every three to five years. Additional drawbacks of the DBS device include the risk of erosion of the leads or hardware, infection, and magnetic sensitivity.

[0013] A prior art deep brain stimulation system is disclosed in U.S. Pat. No. 6,920,359 entitled "Deep Brian Stimulation System for the Treatment of Parkinson's Disease or Other Disorders". The DBS system includes a small, implantable pulse generator implanted directly in the cranium of the patient, thereby eliminating the long lead wires conventionally used. The disclosed system does not provide for the harvesting of energy to power the pulse generator.

[0014] As noted in Table 1, there are several current and potential indications for deep brain stimulation.

[0015] Known systems for providing electrical stimulus to the motor cortex of the brain, such as the Northstar Stroke Recovery Treatment System available from Northstar Neuroscience, Inc., also include an implantable pulse generator implanted in the pectoral area of a patient. A cortical stimulation lead includes an electrode connected to the implantable pulse generator which is used to deliver stimulation to the cortex. The electrode is placed on top of the dura and coupled to the implantable pulse generator by means of a lead which traverses the length of the patient's neck to the patient's pectoral area.

[0016] Motor cortex stimulation (MCS) is a process involving the application of stimulation signals to the motor cortex in the brain of a patient during physical rehabilitation of the disabled region of the body. The MCS system includes a pulse generator connected to a strip electrode that is surgically implanted over a portion of only the motor cortex (precentral gyrus). Because MCS involves the application of stimulation signals to surface regions of the brain rather than deep neural structures, electrode implantation procedures for MCS are significantly less invasive and time consuming than those for DBS. The current evaluation of MCS is for stroke. Stroke-related disabilities affect more than 200,000 people in the U.S. each year. Good results have been reported in MCS treatment of stroke victims. With a MCS device, a stamp-sized electrode is placed on the surface of the brain. This is attached to a wire that goes through the neck to an implantable pulse generator in the pectoral area.

[0017] Neurostimulation and responsive neurostimulation (RNS) are also being tested for the treatment of medically refractory epilepsy. In treating epilepsy, the RNS system can be designed to detect abnormal electrical activity in the brain and respond by delivering electrical stimulation to normalize brain activity before the patient experiences seizure symptoms. For either neurostimulation or RNS for treatment of epilepsy the electrode or electrodes of the device deliver a short train of electrical pulses to the brain near the patient's seizure focus.

[0018] In order to obviate the need for long leads and batteries, attempts have been made in the prior art to transmit energy through space from a base station to a remote station. One such system is disclosed in U.S. Pat. No. 6,289,237 entitled "Apparatus for Energizing a Remote Station and Related Method". The base station transmits energy which may be RF power, light, acoustic, magnetic or other suitable forms of space transmitted or "radiant" energy to the remote station. Within the remote station, the received

energy is converted into DC power which serves to operate the remote station. The source of power for the remote station is the base station and, therefore, there is no need for the remote station to carry an electrical storage device such as a battery. It is suggested that this facilitates the remote station being encapsulated within a suitable protective material, such as a resinous plastic. Homopolymers, elastomers and silicon dioxide are also suggested as suitable materials for such purposes. Further, it is suggested that this facilitates miniaturization of the remote station and placing the remote station in functionally desirable locations which need not be readily accessible. The remote station, for example, could be implanted in a patient.

[0019] The use of a wireless communication link between a base station and transponders in a radio frequency identification system employing modulated back-scattered waves is also known. See Rao, An Overview of Bulk Scattered Radio Frequency Identification System (RFID) IEEE (1999). It has also been suggested to employ a silicon chip in a transponder having a change pump on voltage doubler current. Hornby, RFID Solutions for the Express Parcel and Airline Baggage Industry, Texas Instruments, Limited (Oct. 7, 1999).

[0020] For use in miniaturized electronic chip systems, an electronic article containing a microchip having at least one antenna structured to communicate with an antenna remotely disposed with respect to the microchip is disclosed in U.S. Pat. No. 6,615,074 entitled "Apparatus for Energizing a Remote Station and Related Method". Power enhancement is achieved using a voltage doubler. The antenna of the disclosed apparatus is comparable in volume to a Smart Dust device. Smart Dust is a combination MEMS/Electronic device on the order of 1 mm×1 mm×1 mm.

[0021] What is needed therefore is a brain stimulation device that overcomes the disadvantages of the prior art brain stimulation devices. What is needed is a brain stimulation device that requires a single implantation site and surgery. What is also needed is a brain stimulation device that uses RF energy as a power source. What is further needed is a brain stimulation device that converts RF energy and stores the converted RF energy. What is also needed is a brain stimulation device that is flexible and implantable under the scalp. What is needed is a brain stimulation device that does not require leads or a pulse generator to be placed outside of the head area that are subject to disconnection or breakage. What is also needed is a brain stimulation device for electrical stimulation in the brain that is smaller and more self-contained and that does not require a pulse generator to be implanted elsewhere in the body. What is further needed is a device that is less susceptible to hardware problems or complications. What is needed is a device that has less potential for erosion through the skin. What is also needed is a device that is has a power source that does not need to be replaced.

SUMMARY OF INVENTION

[0022] The device for brain stimulation using RF energy harvesting of the present invention overcomes the disadvantages of the prior art, fulfills the needs in the prior art, and accomplishes its various purposes by providing a brain stimulation device that harvests radio frequency energy and is implantable under the scalp. The brain stimulation device of the invention may include an electrode that penetrates into the brain to provide neurostimulation to the brain. The brain stimulation device may also include an electrode that is used to provide stimulation to the brain cortex.

[0023] In accordance with one aspect of the invention, a device for brain stimulation using radio frequency harvesting includes a circuit implantable under a scalp of a patient, the circuit comprising a radio frequency harvesting power circuit and a stimulation circuit, and a plurality of electrodes coupled to the circuit, the plurality of electrodes providing brain stimulation to targeted areas of the brain. An advantage of this system is that it may use "trickle charging" wherein the device is charged by the harvesting power circuit. Moreover, anther advantage of this invention is the power transmitter which sends power to the device can be used both to send power and to send information.

[0024] There has been outlined, rather broadly, the more important features of the invention in order that the detailed description thereof that follows may be better understood, and in order that the present contribution to the art may be better appreciated. There are, of course, additional features of the invention that will be described below and which will form the subject matter of the claims appended herein.

[0025] In this respect, before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of design and to the arrangement of components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced and carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein, as well as the abstract, are for the purpose of description and should not be regarded as limiting.

[0026] As such, those skilled in the art will appreciate that the conception upon which this disclosure is based may readily be utilized as a basis for the designing of other methods and systems for carrying out the several purposes of the present invention. It is important, therefore, that the claims be regarded as including such equivalent methods and systems insofar as they do not depart from the spirit and scope of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0027] The accompanying drawings, which are incorporated in and form a part of the specification, illustrate the embodiments of the present invention and together with the description, serve to explain the principles of the invention. In the drawings:

DETAILED DESCRIPTION OF THE INVENTION

[0048] A device for deep brain stimulation using RF energy harvesting **200** of he invention is shown implanted under a human scalp in **FIG. 2A**. A flexible, implantable disc-shaped portion **210** having a diameter of about 6 cm and a thickness of between 3 and 4 mm may be formed of a biocompatible material and include circuitry as further described herein. Lead wires **220** may lead from the circuitry and be coupled to electrodes **230** disposed in targeted areas of the brain. Electrodes **230** may include conventional electrodes used for DBS. Neurostimulation lead securement devices **240** including burr hole caps may serve to secure the lead wires **220** to the electrodes. The circuitry may be operable to harvest and store RF energy, control the operation of the device **200** and provide neurostimulation pulses and signals to the targeted areas of the brain.

[0049] A device for cortical brain stimulation using RF energy harvesting **250** of the invention is shown in **FIG. 2B**. The flexible, implantable disc-shaped portion **210** is shown implanted under the scalp. Lead wires **270** may lead from the circuitry of the disc-shaped portion **260** and be coupled to electrodes **280** disposed on the cortical dura.

[0050] With reference to **FIGS. 2C and 2D**, lead securement devices **240** are shown. Lead securement devices **240** may include StimLoc devices available from ign. Lead securement devices **240** may minimize dislodgment of lead wires **220**.

[0051] Lead wires **220** may be coupled to the circuitry of the disc-shaped portion **210** by means of connectors **215**. Connectors **215** may include a plurality of male contacts **217** for providing electrical contact to corresponding female contacts of the circuitry (not shown). A screw hole **219** may be formed in the connector **215** for securing the connectors **215** to the disc-shaped portion **210** and for securing the disc-shaped portion **210** to the skull of the patient.

[0052] The circuitry may include a stimulation circuit **300** as shown in **FIG. 3** and a portion of the power circuit as shown in **FIG. 8A**. The stimulation circuit **300** may include a circuit printed onto the disc-shaped portion **210**. For purposes of illustration, the stimulation circuit **300** may be modeled using discreet components. The stimulation circuit **300** may include a PIC microcontroller **310** such as the PIC16LF87. The microcontroller **310** may manage the internal stimulation circuitry. A low frequency receiver chip **320** such as the ATA5283 may be coupled to the microcontroller **310** and may convert RF communications into programming commands which the microcontroller **310** interprets. An array of analog switches **330** such as the MAX4066 may be coupled to the microcontroller **310** and connect to voltage dividers **340** to output stimulation locations. Analog switches **330** may be coupled to electrodes **230** (**FIG. 2A**) and **260** (**FIG. 2B**).

[0053] According to internal parameters which can be modified via an external RF programming signal, the microcontroller **310** may control analog switch states to determine a voltage applied to any combination of four output locations including four output locations on electrodes **230** and **260**. The maximum possible voltage is determined by the supply voltage to the circuit **300**. A pulsing frequency, nominally 185 Hz, can be adjusted slightly as well as whether a stimulation pulse is applied or not. In order to conserve energy, the microcontroller **310** may enter a standby mode for 4 ms between pulses, greatly reducing power consumption. The microcontroller **310** may be operated with an internal clock frequency of 125 KHz, giving an efficient tradeoff between power conservation and proper functionality. This clock frequency allows pulse durations in increments of 32 micro-seconds. The output pulse duration can be adjusted between ~**60** and ~180 microseconds. With reference to **FIG. 4**, **FIG. 5** and **FIG. 6**, the frequency output, varied voltage output and pulse duration of the microcontroller **310** are shown respectively.

[0054] Every pulsing cycle, the programming input from the low frequency receiver chip **320** may be checked. If a programming signal is present, an input code may be read

sequentially and the specified parameter adjusted to a new value, after which the program continues its pulsing routine.

[0055] The low frequency receiver chip **320** used for receiving external programming commands uses an amplitude shift keying (ASK) protocol. The state of a 125 KHz signal being received determines the output voltage of the low frequency receiver chip **320**: on-high, off-low. While waiting for a signal, the low frequency receiver chip **320** may remain in standby mode, conserving power. Upon the presence of a programming signal, the low frequency receiver chip **320** may wake up and send the coded data to the microcontroller **310**, after which the microcontroller **310** may tell the low frequency receiver chip **320** to enter standby mode again. The programming signal may include a preliminary "on" time to wake up the low frequency receiver chip **320**, a 4-bit header, a 3-bit parameter identifier, and a 4-bit data value. Each bit time is 2 milliseconds, allowing enough time for the microcontroller **310** to process the bit reception before the next bit arrives. An antenna attached to a coil input of the low frequency receiver chip **320** may be a short wire having a strong programming signal.

[0056] Eight analog switches **330** may be used to control the output pulsing. Four switches **330** may determine a path of the selected voltage to the four possible output locations. Each of these may be controlled by one of the microcontroller outputs, which are in turn enabled or disabled depending on the internal variable for output locations. The inputs of the four switches **330** may be attached to the outputs of the other four switches **330**. The inputs of these four switches **330** may all be attached to different voltage dividers **340**, providing four different voltage levels, ranging from three quarters of the supply voltage to the supply voltage maximum of 3V. Each switch **330** may be controlled by an individual microcontroller signal, which also drives the voltage divider **340** for its particular switch **330**. For every pulse, only one of these four microcontroller signals is active, enabling the voltage from its divider **340** to be sent to the output switches **330** and ultimately to the electrodes **230** and **260**. The use of static voltage dividers **340** to provide output voltage scaling may minimize power consumption. In an alternative embodiment of the invention, a custom digital-analog converter could be used to allow for a higher range of stimulation voltages.

[0057] When tested for power consumption, a ~1 Ω resistor was put in series with a powering circuitry described herein. The voltage measured across the resistor while in operation was approximately 17 μV, implying that the DC current required is ~17 μA. At a supply voltage of 3 V, this equates to a power consumption of 51 μW. If operated for 24 hours, the implant would consume a little over 4.4 Joules/day. Typical parameters of a stimulation signal provided for Parkinson's disease are a series of pulses of 120 microsecond duration, 2.5 volts in strength at a repetition rate of 185 pulses per second. Assuming these typical parameters, there are:

185 pulses/second*60 seconds/minute*60 minutes/hour*24 hours/day=$1.5984*10^7$ pulses/day.

With pulse duration of 120 micro seconds, this gives a total energy application duration of $1.5984*10^7*120*10^{6=1918.08}$ seconds. With 2.5 volts and 50 micro amps=120 micro watts, the total energy required for stimulation is $120*10^6$ watts*1918.08 seconds=0.2302 joules per day. As disclosed herein, energy harvesting by the power circuit is on the order of 12-15 joules per day and the stimulation energy required is more than adequately provided by the power circuit.

[0058] An external programmer circuit **700** may include a microcontroller **710** including a PIC16LF87, an inductor/capacitor (LC) oscillating circuit **720** (125 KHz), and an intermediate MOSFET driver **730** including a TC4422 as shown in **FIG. 7**. The MOSFET driver **730** may supply enough energy for driving the LC circuit **720**. When a programming signal is to be sent, a button (not shown) may be pressed, telling the microcontroller **710** to read its inputs and stimulate the MOSFET driver **730** to oscillate the LC circuit **720** according to a communication protocol. Input voltages may be controlled by simple switches. Four switches may dictate the value to be sent, while five switches may dictate which parameter is to be changed. Only one of these switches should be on at one time. A Phidget RFID antenna **740** designed for 125 KHz may be attached to the high voltage side of a capacitor **750** of the LC circuit **720** for sending the programming signal. The circuit **700** may be powered via a 12-Volt wall supply. The 12 V drives the MOSFET driver **730** and is regulated to 5 V for the switches and microcontroller **710**.

[0059] An external powering circuit **800** may include a battery **810** for powering an oscillator **820** which drives a transformer-like setup **830** as shown in **FIG. 8A**. The coils **835** on one side of the transformer **830** may be disposed in a cap worn on the head of a patient, a headband worn on the head of the patient, or on a headboard of a bed in which the patient lies. The coils **840** on the other side of the transformer **830** may be coupled to the stimulation circuit **300** and may be disposed proximate the coils **835**. An AC signal coming from coil **840** may be amplified and rectified through a charge pump **850** having three stages, after which a voltage may be clamped with a regulator **860** to prevent spiking. A control circuit **870** may control operation of the voltage regulator **860**.

[0060] The oscillator **820** may include an LTC6900. This oscillator **820** produces a 50% duty cycle square wave to drive the primary coil **835** of the transformer **830** and requires only a potentiometer for adjusting the frequency. The charge pump **850** may be a Cockroft Walton voltage multiplier, utilizing a ladder of diodes and capacitors to rectify and amplify the signal. The amplification depends on the number of stages used. Three stages have been found to be enough for a substantial voltage multiplication across a load of 200 KΩ. The capacitors may be 0.1-μF each and the diodes may include BAT54SW surface mount diodes with a forward voltage drop of ~0.24-V. The regulator **860** may include an LT1521-3, which clamps a higher input voltage to 3 V.

[0061] Previous empirical testing showed square coils (both primary **835** and secondary **840**), 1 in.×1 in., with 5 turns each are effective for transferring enough energy to power the stimulation circuit **300**. Coils **840** are shown in PCB layout in **FIG. 9** and coils **835** are shown in PCB layout in **FIG. 10**.

[0062] The optimal frequency depends on the dielectric and distance between coils **835** and **840**. Frequencies in the range of 2 MHz to 15 MHz may be used. The oscillator **820** can be powered with 3 AAA batteries (4.5 V). In examining

the actual signal through the primary coil **835**, the voltage waveforms in **FIG. 11** and **FIG. 12** were obtained. **FIG. 11** shows the output voltage from the oscillator **820**. **FIG. 12** shows the voltage across the primary coil series resistance, from which the RMS current is calculated to be 29.36 mA_{RMS}.

[**0063**] The embodiment described above provides for near field harvesting and includes inductive coupling between coils **835** and **840**. With reference to **FIG. 8B** and in an alternative embodiment of the invention, the power circuit **865** for powering the stimulation circuit **300** may be non-inductively coupled to an external source of RF energy **880**. In this far field embodiment, the power circuit **865** may be disposed in a wrist band worn by the patient, in a room transmitter or in a transmitter disposed in a building occupied by the patient. In yet another alternative embodiment of the invention, the power circuit **865** may harvest ambient RF energy such as energy transmitted in space by using an inherently tuned antenna as described in U.S. Pat. No. 6,856,291, the description of which is incorporated by reference in its entirety herein. Furthermore, a rechargeable battery or other storage device (not shown) may be employed to store harvested energy. “Non-inductive” as described herein being directed RF.

[**0064**] To demonstrate the effectiveness of the powering and programming schemes through tissue, the device **200** was tested through swine skin. Clear tape was used to cover the conductive surfaces on the primary coil **835** and the secondary coil **840** to prevent interaction with the moisture on the skin. This tape had negligible effect on the inductive coupling.

[**0065**] Three different tests were performed, each following the same procedure. At a certain separation, the voltage powering the primary coil oscillator **820** was adjusted and the maximum output voltage from the secondary coil voltage regulator **860** was measured. The primary coil oscillator voltage started at 5 V and was decreased in increments of 0.1 V until the maximum regulator output voltage had reached a steady minimum.

[**0066**] The first test was performed with no skin between the transformer coils **835** and **840**. Data was acquired at separations of 5 mm, 7 mm, and 10 mm, values chosen based on the common range of human scalp thickness. The second test used fresh swine skin of thicknesses 5 mm and 7 mm between the transformer coils **835** and **840**. The test was interrupted, preventing the testing of 10 mm thick skin. The third test used the same pieces of swine skin, 5, 7, and 10 mm thick, after they had been frozen and thawed.

[**0067**] **FIG. 13** shows the results from the first two tests for comparison purposes. The presence of the skin reduced the inductive coupling between the coils, and hence the possible maximum output voltage in the range of 1.5-3.8 V. At 4.0 V and above, the maximum output voltage of ~3 V is obtainable even with the presence of the skin.

[**0068**] The same pieces of skin were tested a second time due to interruption of the first test. However, they had all been frozen and thawed in the interim, affecting the results slightly. **FIG. 14** shows the effect that the freezing and thawing of the skin had on the energy transfer of the transformer coils. Both the 7- and 10-mm thick pieces of skin reduced the inductive coupling, but the 5-mm skin actually improved in performance. This may be due to the presence of a layer of fat in both the 7- and 10-mm pieces that is absent in the 5-mm piece.

[**0069**] Another test was performed to find the effect of the skin over time. The stimulus for this test was the degrading performance of the 10-mm thick skin over time during the interrupted test mentioned above. For this test, the 7-mm thick piece of skin was used between the primary and secondary coil. The frequency was adjusted to produce a maximum output voltage, which was measured successively over a period of time. The results shown in **FIG. 15** support the fact that performance does not degrade over time. The slight drop in output voltage is likely due to the mechanical nature of the frequency-tuning potentiometer. Notice that the output voltage reaches a steady value and remains constant after that point.

[**0070**] In order to demonstrate the concept and functionality of the device **200**, a model **1600** was created as shown in **FIG. 16**. The stimulation circuit **300** was put on top of a Styrofoam head **1610** with wires running down through the bottom for power- and pulse-monitoring purposes. An ABS Plastic cap (not shown) was made to simulate the head’s scalp, covering the stimulation circuit **300**. The primary powering coil **835** with the batteries **810** was secured in a hat **1620** over the position of the stimulation circuit **300** to provide for near field inductive coupling.

[**0071**] The device **200** was tested on a cadaver head to show that a signal may be generated through the scalp and to demonstrate the programmability of the device **200** during stimulation. First, an incision was made in the scalp of the cadaver head. The secondary coil **840** was inserted and placed on the skull and the incision was sewn, leaving the lead wires **220** of the circuit exposed. Six wires were used on the implanted circuitry, four representing the electrodes **230**, which were connected to an oscilloscope and two wires for power and ground. The primary coil **835** was then taped on the scalp directly on top of the implanted circuitry and connected to a power supply.

[**0072**] The experiment began by demonstrating the programmability of the stimulation circuit **300**. Four parameters were varied and displayed on the oscilloscope; pulse width (60, 120 and 180 micro seconds), amplitude (2.34V, 2.75V, 2.94V, 3.13 V), frequency (191 and 194 Hz) and the shifting from one stimulating probe to another (i.e. probe **1** to probe **2** or probe **1** to all four probes). A 10K OHM resistor was used to represent the brain resistance, however this resistance is higher than the resistance for the brain (900 to 1100 Ohms), but a 10 k Ohm resistor was used to ensure there was enough power.

[**0073**] Next, several voltages were tested to determine the output source voltage of the power circuit **865**. Initially, the power supply connected to the primary coil **835** was set at 5 V and was decremented by 0.1 V to 1.2 V. The voltage on the secondary coil **840** was clamped so as not to exceed 3V. As the voltage decreased on the power supply, the output voltage on the secondary coil **840** was steady at 3 V until it declined around 2.2 V. Once the voltage decreased from 3V, a potentiometer was adjusted to obtain the maximum voltage. The data obtained shows the when the voltage drops, the amplitude voltage and frequency drop off as well.

[**0074**] The device for brain stimulation using RF harvesting of the present invention provides a brain stimulation device that requires a single implantation site and surgery to thereby reduce both the cost and trauma to the patient of the implantation procedure. The brain stimulation device further uses RF energy as a power source to eliminate the need for a battery implanted in the pectoral area of the patient. The brain stimulation device further converts RF energy and

stores the converted RF energy for use in stimulation of targeted brain areas. The brain stimulation device is flexible and implantable under the scalp to minimize discomfort for the patient.

[0075] The foregoing description of the embodiments of the invention has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed. Many modifications and variations are possible in light of the above teaching. It is intended that the scope of the invention be limited not by this detailed description, but rather by the claims appended hereto.

We claim:

1. A system for brain stimulation using radio frequency harvesting comprising:

a device implantable under a scalp of a patient, the device comprising a radio frequency harvesting power circuit and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

2. The system of claim 1, wherein the device is fabricated from a biocompatible substrate.

3. The system of claim 1, wherein the device is flexible and conformable to a shape of the scalp.

4. The system of claim 1, wherein the power circuit comprises a charge pump inductively coupled to a primary coil of an external power circuit.

5. The system of claim 1, wherein the power circuit comprises an inherently tuned antenna for harvesting energy transmitted in space.

6. The system of claim 1, wherein the at least one electrode provides deep brain stimulation.

7. The system of claim 1, wherein the at least one electrode provides cortical stimulation.

8. The system of claim 1, further comprising a programming circuit operable to control the stimulation circuit.

9. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit voltage output.

10. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit output pulse width.

11. The system of claim 8, wherein the programming circuit is operable to control a stimulation circuit output frequency.

12. The system of claim 1, further comprising an energy storage device coupled to the device.

13. A system for brain stimulation comprising:

a device implantable under a scalp of a patient, the device comprising a coupled power circuit and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

14. The system of claim 13, wherein the coupled power circuit is inductively coupled.

15. The system of claim 13, wherein the coupled power circuit is non-inductively coupled.

16. A system for brain stimulation comprising:

a device implantable under a scalp of a patient, the device comprising a power circuit powered by ambient radio frequency energy and a stimulation circuit; and

at least one electrode coupled to the stimulation circuit, the at least one electrode providing brain stimulation to targeted areas of the brain.

17. The system of claim 1, wherein the at least one electrode provides brain stimulation to targeted areas of the brain in response to signals received from the stimulation circuit.

18. A method of providing brain stimulation, comprising:

harvesting power in a power harvesting circuit in a device implantable under the scalp of a patient; and

providing brain stimulation to targeted areas of the brain with at least one electrode connected to the power harvesting circuit.

19. The method of claim 18, wherein the power harvesting circuit harvests radio frequency energy.

20. The method of claim 18, wherein the power harvesting circuit harvests energy by an inductively coupled power circuit in the device.

21. The method of claim 18, wherein the power harvesting circuit harvests energy by a non-inductively coupled power circuit in the device.

22. The method of claim 18, wherein the brain stimulation is used to treat Parkinson's disease.

23. The method of claim 18, wherein the brain stimulation is used to treat stroke patients.

Building a crystal radio set

Updated Tuesday 3rd July 2007

For many of the original teenagers, home-built crystal radios gave them their first contact with the world beyond their bedrooms. Here, Fraser Robertson describes how to make your own.

Share this article

Author

A crystal set is the most basic type of radio receiver. It is capable of receiving AM (amplitude modulated) transmissions, which are generally found on the long, medium and short wave bands.

The magic of the crystal set is that no power source is required; a tiny fraction of the transmitted signal provides sufficient power for the signal to be heard. What follows, while listing the parts you'll need, isn't a step-by-step how to guide, as part of the fun in building a crystal set is experimenting and optimising performance.

Aerial

Unless the crystal set is very close to the transmitter, an aerial, (or antenna) will be required in order to receive a big enough signal for the crystal set to work. Generally the aerial will be a length of wire, which should be as long and as high as possible.

A wire strung from an upstairs window to a distant tree will work well; say 30 metres long and seven metres high. The type of wire is not critical, but PVC covered stranded copper wire of about 2 milimetres diameter will work well.

If the wire is too thin it may break in the wind, and/or birds may fly into it; too thick and it will sag under its own weight.

The aerial should be insulated at each end from its support, a short length of washing line or other non-conductive cord can be used. An effective aerial will produce about one tenth of a volt radio frequency (RF), which will result in good reception.

Earth

An earth connection is required to complete the aerial circuit. This can be a length of copper pipe driven into the ground, or a length of buried un-insulated wire.

As with the aerial, a better earth connection will improve reception. It is possible to connect to a metal heating or water pipe, but **this is not recommended on safety grounds** should there be an electrical fault. For the same reason, **the mains earth** should not be used.

When the crystal set is not in use the aerial should be connected directly to the earth connection. This will prevent any possible static build up on the aerial.

Tuned circuit

The aerial and earth are connected across a parallel tuned circuit. The purpose of this is to select the wanted station.

A simple crystal set will not have good selectivity so if two strong signals are received on nearby frequencies it will not be possible to separate them.

The tuned circuit comprises a coil (inductor) and a capacitor, which is usually variable for tuning. Pre-wound ferrite rod coils can be bought, or you can wind your own: for example, for medium wave, 100 turns of 0.5 milimetre enameled copper wire wound on a toilet roll or similar sized non-metallic former, twisted/tapped every ten turns.

Kathy's Carriacou diary: Arrival

Bang Goes The Theory: Show me the bunny

Sir Bernard Lovell: An appreciation

The science of making musical instruments

The greater number of turns, the longer the wavelength (lower frequency), so a coil for long wave will require more turns. If using a pre-wound ferrite rod, ignore the small link windings.

An air spaced variable capacitor (with a value around 500 picofarad) removed from an old radio is ideal, or alternatively a small polyvaricon capacitor as used in transistor radios.

Variable capacitors often have two or more capacitors in one (known as **ganged**), in which case these can be connected together to increase the maximum capacitance (lower the tuning frequency).

Some variable capacitors also have FM (VHF) tuning sections included, which can be ignored. If a variable capacitor is not available, a fixed capacitor can be used (e.g. 150 picofarad - 470 picofarad), with the tuning adjusted by changing taps on the coil. In which case, taps every five turns would be useful.

Detector

The purpose of the detector is to recover the audio signal (waveform) from the radio frequency signal. Early crystal sets used an adjustable ‘cats whisker’ detector, but a germanium or Schottky diode is now used, examples are OA90, OA91, BAT81, BAT85, 1N34, 1N5711. Any one of these can be used.

Silicon diodes, (such as 1N4148) do not work as well due to their higher forward voltage drop. Modern zero gate threshold voltage FETs can be used for better sensitivity, although these are not readily available in small quantities. The detector diode is polarized (directional), but in the crystal set circuit it does not matter which way round it is connected.

Headphones

Traditional crystal sets used sensitive high impedance headphones, typically several thousand Ohms, which are hard to obtain now. A crystal earpiece can be used, or a sensitive pair of walkman style headphones (usually 32+32 Ohms) connected through a transformer (e.g. type LT700) to raise the impedance. Low impedance headphones will ‘load’ the tuned circuit excessively.

Look for headphones with a high sensitivity figure, for example 115 decibels - a higher number indicates higher sensitivity; CPC AV03626 106 decibel headphones work well. Be aware that a higher quoted decibel specification does not always guarantee higher sensitivity in practice.

Note that if a crystal earpiece is used, a resistor (such as a 47k Ohms) may need to be connected across it to provide a DC path for the detector diode.

Construction

The fine detail here is left to the builder. Component leads can be soldered, or twisted together, or ‘crocodile clips’ can be used to make connections.

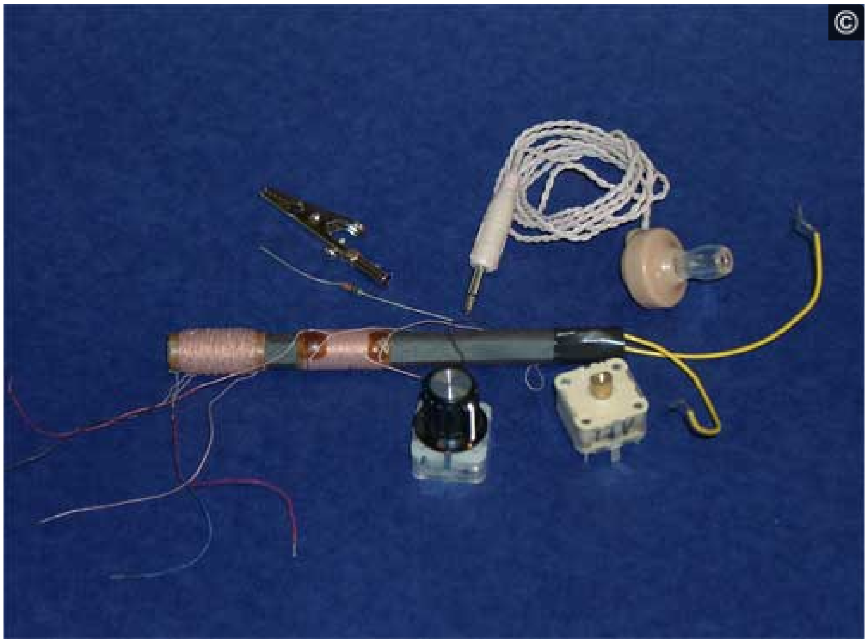
TITLE
OU BBC Crystal Set

The diagram above, and the photograph at the top of the page, offers some guidance. **You can download a larger pdf of the diagram by clicking here**.



This photograph shows examples of alternative suggested parts. The components can be lashed together initially for experimentation, then connected more permanently and housed in any suitable enclosure once the crystal set is working.

Typical performance and troubleshooting

In the UK it will normally be possible to pick up two or three stations on medium wave, and/or BBC Radio 4 from Droitwich on long wave. If nothing at all is heard check:

- that all connections are sound, and ensure the enamel insulation on coil wire has been removed by being scraped off where connections are made
- that the correct connections for each component have been used
- that the tuning capacitor vanes are not bent and touching together.

If you get weak reception it may be that you need to improve the aerial / earth connections, or try a different pair of headphones.

(57) **ABSTRACT**

A system for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current includes a first portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the first portal. The system comprises a second portal separate and apart from the first portal with a gap between the first portal and the second portal, the second portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current after the device has passed through the first portal and the gap and is in the second portal. A method for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current is also disclosed.

RADIO-FREQUENCY (RF) POWER PORTAL

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Patent Application Ser. No. 60/738,523, filed Nov. 21, 2005.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to a system for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current. More specifically, the present invention relates to a system for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current when it is in a portal in which wireless energy is transmitted for the energy harvester of the mobile device.

[0004] 2. Description of Related Art

[0005] As processor capabilities have expanded and power requirements have decreased, there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones and wireless keyboards to building sensors and active Radio Frequency Identification (RFID) tags.

[0006] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily using batteries as the key design parameter. While the performance of processors and portable devices has been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at a measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not meet the lifetime cost and maintenance requirements for applications that require a large number of untethered devices such as logistics and building automation. Today's devices that need two-way communication require scheduled maintenance every three to **18** months to replace or recharge the device's power source (typically a battery). One-way devices that simply broadcast their status without receiving any signals, such as automated utility meter readers, have a better battery life typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and can be disruptive to the entire system that a device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0007] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the environment. The harnessed energy would then either directly power an untethered device or augment a power supply. However, this ideal solution may not always be practical to implement due to low energy in the environment, and site restrictions may limit the ability to use a dedicated energy supply. The proposed invention takes these factors into account and provides a solution for both the ideal situation and also for more restrictive circumstances.

[0008] U.S. Pat. No. 6,127,799 discloses a method and apparatus for wireless powering and recharging by use of an electromagnetic field with an antenna. The antenna may be one or more dipole antennas that are combined to form at least two subsets of dipole antenna element array, wherein one subset may be oriented at an acute or a right angle with respect to at least one other subset. The technology disclosed in U.S. Pat. No. 6,127,799 is limited by the fact that the power conversion efficiency of the antenna array is dependent on the number of dipoles. Additionally, U.S. Pat. No. 6,127,799 discloses the use of dipole antennas, which may not be practical for most battery-operated devices due to the size of the antenna and antenna array. This prior disclosure, states that the dipole antennas are used to cover more than one side of a battery that has a width of 12.5 cm which makes in impractical for certain devices and battery sizes. There are also limitations on the battery that can be used with the prior disclosure due to metal pieces inside the battery, which tend to absorb RF energy. The invention disclosed herein does not suffer from the described limitations of the antenna and battery and is applicable with any antenna and battery type.

[0009] U.S. Pat. No. 5,994,871 discloses a system for charging a secondary cell using transmitted microwave energy, however, it relies solely on the use of an existing microwave oven as the charging means.

[0010] U.S. Pat. No. 5,982,139 discloses a remote charging system for a vehicle capable of transmitting electrical energy to the electrical storage device via a wireless energy beam. The referenced patent relies on the beam being able to track the vehicle or vehicles, which limits the number of devices (vehicles) by the number of beams available at a power transmitting location. The invention disclosed herein does not suffer from this limitation and is capable of transmitting power to many devices using a single beam.

[0011] U.S. Pat. Nos. 5,411,537, 5,733,313, and 5,769,877 describe systems for providing power to implantable biomedical devices by use of electromagnetic induction techniques using power transmitting and receiving coils. The devices in these patents are limited by the fact that they can only receive power in the inductive or near-field region. Additionally, the implanted devices have a dedicated transmitter with the purpose of supplying power solely to a single implanted device.

BRIEF SUMMARY OF THE INVENTION

[0012] The present invention pertains to a system for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current. The system comprises a first portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the first portal. The system comprises a second portal separate and apart from the first portal with a gap between the first portal and the second portal, the second portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current after the device has passed through the first portal and the gap and is in the second portal.

[0013] The present invention pertains to a method for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current. The method comprises the steps of moving the device into a first portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the first portal. There is the step of converting the wireless energy transmitted in the first portal by the energy harvester of the mobile device into current when the device is in the first portal. There is the step of moving the device from the first portal to a second portal separate and apart from the first portal through a gap between the first portal and the second portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the second portal. There is the step of converting the wireless energy transmitted in the second portal by the energy harvester of the mobile device into current when the device is in the second portal.

[0014] The present invention pertains to a method for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current. The method comprises the steps of moving the device into a portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the portal. There is the step of converting the wireless energy transmitted in the portal by the energy harvester of the mobile device into current when the device is in the portal. There is the step of moving the device out of the portal. There is the step of moving the device back into the portal for the energy harvester of the mobile device to receive and convert the energy into current when the device is in the portal. There is the step of converting the wireless energy transmitted in the portal by the energy harvester of the mobile device into current when the device is back in the portal.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0015] FIG. **1** shows a single RF power portal with an associated coverage area.

[0016] FIG. **2** shows multiple RF power portals with associated coverage areas and separated by a region without coverage.

[0017] FIG. **3** shows a single RF power portal with an associated coverage area with multiple devices.

[0018] FIG. **4** shows multiple RF power portals with associated coverage areas with multiple devices and separated by a region without coverage.

[0019] FIG. **5** shows multiple RF power portals with associated coverage areas with multiple devices and each separated by regions without coverage.

[0020] FIG. **6** shows an RF power portal implemented at a loading dock.

[0021] FIG. **7** shows an expanded RF power portal implemented in a loading dock.

[0022] FIG. **8** shows the implementation of a multiple load dock example.

DETAILED DESCRIPTION OF THE INVENTION

[0023] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0024] For purposes of the description hereinafter, the terms “upper”, “lower”, “right”, “left”, “vertical”, “horizontal”, “top”, “bottom”, and derivatives thereof shall relate to the invention as it is oriented in the drawing figures. However, it is to be understood that the invention may assume various alternative variations and step sequences, except where expressly specified to the contrary. It is also to be understood that the specific devices and processes illustrated in the attached drawings, and described in the following specification, are simply exemplary embodiments of the invention. Hence, specific dimensions and other physical characteristics related to the embodiments disclosed herein are not to be considered as limiting.

[0025] Referring now to the drawings wherein like reference numerals refer to similar or identical parts throughout the several views, and more specifically to FIGS. **1** and **2** thereof, there is shown a system **10** for powering a mobile device **12** having an energy harvester **14** which receives wireless energy and converts the energy into current. The system **10** comprises a first portal **16** in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current when the device **12** is in the first portal **16**. The system **10** comprises a second portal **18** separate and apart from the first portal **16** with a gap **20** between the first portal **16** and the second portal **18**, the second portal **18** in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current after the device **12** has passed through the first portal **16** and the gap **20** and is in the second portal **18**.

[0026] A method and apparatus for high efficiency rectification for various loads (energy harvester and energy harvesting), which are suitable for receiving the RF power distributed by the present invention, have been discussed in detail in U.S. Provisional Patent Application No. 60/729,792 and U.S. patent application Ser. No. 11/584,983, which are incorporated herein by reference.

[0027] Preferably, the portal is defined by a minimum field strength. The portal preferably has at least one wireless energy transmitter **22**, and could have a plurality of wireless transmitters. Preferably, the wireless energy transmitter **22** produces pulses of energy. The system **10** preferably includes a third portal **24** separate and apart from the first portal **16** and the second portal **18** with a second gap **26** between the third portal **24** and the second portal **18**. The third portal **24** in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current after the device **12** has passed through the second portal **18** and the second gap **26** and is in the third portal **24**. Preferably, each portal has a wireless energy transmitter **22**. The device can include a charge storage element **34** in the device in communication with the energy harvester to receive the current from the harvester to charge the storage element **34**.

[0028] The present invention pertains to a method for powering a mobile device **12** having an energy harvester **14** which receives wireless energy and converts the energy into current. The method comprises the steps of moving the device **12** into a first portal **16** in which wireless energy is transmitted for the energy harvester **14** of the mobile device

12 to receive and convert it into current when the device **12** is in the first portal **16**. There is the step of converting the wireless energy transmitted in the first portal **16** by the energy harvester **14** of the mobile device **12** into current when the device **12** is in the first portal **16**. There is the step of moving the device **12** from the first portal **16** to a second portal **18** separate and apart from the first portal **16** through a gap **20** between the first portal **16** and the second portal **18** in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current when the device **12** is in the second portal **18**. There is the step of converting the wireless energy transmitted in the second portal **18** by the energy harvester **14** of the mobile device **12** into current when the device **12** is in the second portal **18**.

[**0029**] There can be the step of communicating with the device **12** with a communication transceiver **36**. The communication transceiver **36** can be co-located with a wireless energy transmitter **22**. There can be the step of charging a charge storage element **34** in the device.

[**0030**] Preferably, there is the step of moving the device **12** from the second portal **18** to a third portal **24** separate and apart from the first portal **16** and the second portal **18** through a second gap **26** between the second portal **18** and the third portal **24** in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current when the device **12** is in the third portal **24**. The moving the device **12** into the first portal **16** step preferably includes the step of moving the device **12** into the first portal **16** which is at a loading dock **28**.

[**0031**] The present invention pertains to a method for powering a mobile device **12** having an energy harvester **14** which receives wireless energy and converts the energy into current. The method comprises the steps of moving the device **12** into a portal in which wireless energy is transmitted for the energy harvester **14** of the mobile device **12** to receive and convert it into current when the device **12** is in the portal. There is the step of converting the wireless energy transmitted in the portal by the energy harvester **14** of the mobile device **12** into current when the device **12** is in the portal. There is the step of moving the device **12** out of the portal. There is the step of moving the device **12** back into the portal for the energy harvester **14** of the mobile device **12** to receive and convert the energy into current when the device **12** is in the portal. There is the step of converting the wireless energy transmitted in the portal by the energy harvester **14** of the mobile device **12** into current when the device **12** is back in the portal.

[**0032**] Preferably, the portal is defined by a minimum field strength. The portal preferably has a wireless energy transmitter **22**. There can be the step of communicating with the device **12** with a communication transceiver **36**. The communication transceiver **36** can be co-located with the energy transmitter **22**.

[**0033**] Preferably, the wireless energy transmitter **22** produces pulses of energy. The moving the device **12** into the portal step preferably includes the step of moving the device **12** into the portal which is at a loading dock **28**. Alternatively, the device **12** can be an RFID tag, and there can be the step of communicating data from the RFID tag to a data receiver **38**.

[**0034**] The moving the device **12** into the portal step includes the step of moving the device **12** into the portal which is at a recharging cabinet. There can be the step of eliminating interference with other equipment and protecting humans from the energy with shielding in the recharging cabinet.

[**0035**] Untethered devices **12** can be classified into two categories, stationary and mobile. A stationary device **12** is defined as, but not limited to, a device **12** that is designed not to move. A mobile device **12** is defined as, but not limited to, a device **12** that is designed with the ability to move or be moved. Mobile devices pose a problem when trying to implement a powering solution due to the constant change in the device **12** location. One solution for mobile devices was proposed in U.S. provisional patent application 60/683,991, "Power Transmission Network"; in U.S patent application Ser. No. 11/438,508, "Power Transmission Network"; and in U.S. provisional patent application 60/763,582, "Power Transmission Network and Method", all of which are incorporated by reference herein. The application describes how a Radio Frequency (RF) power-harvesting network could be setup to provide power to devices within a specific area. However, mobile devices may not always be confined to the coverage area. In this situation, once the device **12** leaves the area, it will no longer receive power, making the device **12** rely solely on its power supply, if one exists. The proposed invention addresses this issue by creating an RF power portal. The purpose of the power portal is to provide a device **12** with enough operating power so the device **12** can function while it is outside the coverage area until it needs to return to a power portal to obtain additional power. This method is analogous to recharging a cell phone. Once the battery charger has charged the battery, the cell phone can be removed from the charger. The cell phone is then free to move away from the charger and operate until it uses the charge stored in the battery. At this point, the cell phone must return to the battery charger to obtain more power. In this example, the RF power portal is analogous to the cell phone battery charger.

[**0036**] In the previous example, the cell phone must be directly connected (wired) to the charger in order for charge to be transferred. The proposed invention eliminates the need for a wired connection in order to transfer charge. The charge is transferred to the device **12** from the RF power portal preferably in the form of electromagnetic waves or RF energy. The device **12** contains an energy harvester **14**, which preferably is used to convert the electromagnetic waves captured by the antenna into usable current such as Direct Current (DC). This invention should not be confused with power transfer by inductive coupling, which requires the device **12** to be relatively close to the power transmission source. The RFID Handbook by the author Klaus Finkenzeller defines the inductive coupling region as distance between the transmitter and receiver of less than 0.16 times lambda where lambda is the wavelength of the RF wave. The proposed invention can obtain power in the near-field (sometimes referred to as inductive) region as well as the far-field region. The far-field region is distances greater than 0.16 times lambda. This means the RF power portal can cover a large area, such as entire room, or be localized to a portion of a room, such as around an office desk. One method of transmitting RF energy was described in U.S. provisional patent application 60/656,165, "Method, Apparatus and System for Power Transmission"; in U.S patent application Ser. No. 11/356,892, "Method, Apparatus and System for Power Transmission"; and in U.S. provisional patent application 60/758,018, “Pulse Transmission Method”, all of which are incorporated by reference herein, which describes the use of RF energy pulses to increase the efficiency of the energy harvester **14** in the receiving device **12**. The pulsing method can also be used with the invention proposed herein to provide a larger coverage area than those available for Continuous Wave (CW) implementations. The coverage area can be defined by an instantaneous, peak, or average field strength or power density with respect the power transmitter. As an example, the energy harvester **14** may require an electric field strength of one volt per meter in order to convert the electromagnetic energy to DC at an acceptable efficiency. For a CW power transmitter, this field strength may correspond to a distance from the power transmitter of six feet. However, the device **12** may be located at ten feet meaning it is outside the CW coverage area. If pulsing is used, a larger amount of power can be transmitter at a particular duty cycle in order to average to the same amount of power as the CW case, however, the peak electric field will be greater than the CW case at six feet although the average is the same. The electric field strength at ten feet will then have a peak value greater than one volt per meter, which will enable the energy harvester **14** to capture and convert energy.

[**0037**] The RF power portal can be configured in numerous ways. Several of these configurations are presented and should not be considered limiting but rather examples of the invention. The first embodiment of the RF power portal is a single transmitter having a single coverage area, AREA **1**. A coverage area (or volume) is defined by a minimum electric, magnetic, and/or electromagnetic field strength and is represented as a dashed line in all figures. It should be noted that the figures illustrate a circular coverage area, however, the shape of the coverage area may take on other shapes for different antenna types and environments. As an example, Area **1** in FIG. **1** may be defined as the area in which the electric field strength generated by Transmitter **1** (TX**1**) is greater than two volts per meter (2 V/m). It should be noted that TX**1** in FIG. **1** preferably contains an RF transmitter and an antenna. Subsequent figures may use the same transmitter block or may separate the transmitter and antenna. The transmitter will be represented in the figures by a TX block with or without a trailing number such as TX, TX**1**, TX**2**, etc.

[**0038**] For the configuration in FIG. **1**, the device **12**, RX**1**, is receiving operational and recharging power from the RF field produced by the RF power transmitter, TX**1**, while it is in the coverage area, AREA**1**. The device **12**, RX**1**, at time t**1** in FIG. **1**, is receiving not only operational power but also additional charge that may be stored in a charge storage element such as, but not limited to, a battery and/or capacitor, or other charge storage element, for use if the device **12** leaves the coverage area, AREA**1**. As an example, at time t**2** in FIG. **1**, the device **12** is operating from power captured while in the coverage area. When the charge captured at time t**1** has been depleted the device **12** is operating from charge stored previously in the charge storage element. As can be seen by examining FIG. **1**, the device **12** can continuously operate if the device **12** periodically returns to the coverage area to obtain additional charge. As an example, the device **12** may require 1 joule of energy to operate for a twenty-four hour period. If the device **12** then returns to the coverage area after the twenty-four hour period, it may be able to capture an amount of power equivalent to that used in the twenty-four hour period, 1 joule, by remaining in the coverage area for one hour. In this example, the device **12** can capture all charge needed for operation from the RF power transmitter, TX**1**. There may, however, be applications where the device **12** is away from the coverage area for longer periods of time than twenty-four hours, which can be combated by increasing the time the device **12** must remain in the coverage area. There may also be cases where the lifetime of the device **12** is a known finite value and therefore, the device **12** may not need to capture the total amount of charge used in the time away from the coverage area. Rather, the device **12** needs to capture an amount less than the charge used but enough to insure operation for the lifetime of the device’s battery or other storage element. There may also be instances where the device **12** may leave the coverage area for an unknown extended period of time. In which case, the RF power transmitter must fully charge the device **12** to the peak capacity of the charge storage element to insure the device **12** can function until it is able to return to the RF power portal.

[**0039**] Another embodiment of the RF power portal is shown in FIG. **2**. FIG. **2** shows multiple coverage areas separated by a distance, D. In this case, the device **12** may obtain power in the first coverage area, AREA**1**, at time t**1** from the RF power transmitter, TX**1**, for the purpose of having enough power to travel the distance, D, to the second coverage area, AREA**2**, where at time t**3** the device **12** would be able to capture charge from RF power transmitter, TX**2**, to replace the charge used during time t**2** outside the coverage areas, AREA**1** and AREA**2**. As an example, the device **12** may take twenty-four hours to travel the distance, D, between the first coverage area and the second coverage area and may use 10 joules of energy while outside the coverage areas. The first RF power transmitter, TX**1**, must therefore supply the device **12** with 10 joules of energy in order to travel the distance, D, between the two coverage areas. Once the device **12** reaches the second coverage area, AREA**2**, it can capture an amount of power equivalent to that used in the twenty-four hour period, 10 joules, by remaining in the coverage area for a given period of time.

[**0040**] It should be noted that the inventions in FIG. **1** and FIG. **2** may be used with more than one device **12** which is shown in FIG. **3** and FIG. **4**, respectively.

[**0041**] It should be noted that the invention may be extended to include multiple RF power transmitters each with an associated coverage area with each area having any number of devices which can move in and out of the coverage areas provided by the RF power transmitters. An expanded version of the invention is shown in FIG. **5**.

[**0042**] If found to be advantageous, the device **12** may communicate with a communication transceiver **36** located inside or outside the coverage area(s) while the device **12** is inside or outside the coverage area(s). A communication transceiver **36** is defined as a transmitter and/or receiver using wireless communication techniques to transfer data. A practical implementation of the invention with a communication transceiver **36** would be to have the RF power transmitter collocated with the communication transceiver **36** and have the device **12** communicate while it is inside the coverage area. Communication inside the coverage area allows the device **12** to use additional power to transmit/receive data because the RF power transmitter is supplying the device **12** with additional power to recharge its storage element, which could then be used to supply the additional power to turn on the communication transceiver **36**. The device **12** may transmit multiple data readings collected while it was outside the range of the communication transceiver **36**.

[**0043**] Specifically, the RF power portal is a defined area (or volume) where a device **12** can receive and store operational power for current and later use inside or outside of the coverage area. More specifically, the RF power portal may contain at least one RF power transmitter with at least one associated antenna that defines a coverage area where mobile devices with energy harvesters **14** may be located. The portal is designed so the device **12** will be able to capture enough power from the transmitter for operation during its time away from the RF power portal. To give farther insight into the described invention, several examples of implementation will be given. The portal can have a plurality of wireless energy transmitters, all of which are the same, or some of which are different in regard to the amplitude of the energy they output and/or the polarization, frequency or pulse of the output.

[**0044**] One implementation of an RF power portal is a battery recharging cabinet. The cabinet may be a new or existing structure where one or more RF transmitters are located in order to provide power to one or more devices. The cabinet or structure may or may not be shielded to minimize RF interference depending on its environment. A specific example of the battery recharging cabinet was designed for a hospital environment. The cabinet was shielded to eliminate interference with hospital equipment and was designed to recharge the battery or batteries in a patient-tracking device **12**. The shielding also allows the power to be elevated without risk of exposing humans to unsafe levels of RF energy as regulated by the Federal Communications Commission (FCC) and other standards bodies. The recharging cabinet was designed to eliminate the need for a hardwired recharging device **12** and to allow the nurse or other staff member to simply place the tracking device **12** inside the cabinet in any direction rather than in a recharging cradle. After a predetermined charging period, the device **12** can be removed from the cabinet for use in the hospital. The door of the cabinet was connected to a switch to control the operation of the transmitter, but this does not have to be the case. When the door is open, the transmitter power was turned off to eliminate any interference with hospital equipment. The power could also be turned down instead of off. The device **12** was required to operate for several days before recharging was required. The output power of the transmitter inside the cabinet was designed to provide the battery with enough charge to supply the required power to the device **12** for the average stay of a patient. The average patient stay was chosen because the device **12** can operate longer if needed. As an example, the average patient stay may be two days meaning the battery recharging cabinet will supply the battery with two days of charge. The patient, however, may stay in the hospital for five days. This does not mean the device **12** will fail to operate after the second day. After the second day, the device **12** will run off of the reserve charge stored in the battery, and the battery will begin to drain below a reference level. When the device **12** is returned to the cabinet after the fifth day, it will receive enough charge to operate for an additional two days. However, the next patient may only have a stay of one day. As can be seen by using the average, the power stored in the battery will average to the reference level allowing the device **12** to operate without problems.

[**0045**] It may also be advantageous to implement the system **10** described above in an existing structure within the hospital. One existing structure that was explored was the sterilization equipment. The patient-tracking device **12** needs to be sterilized after each use. The sterilization may be performed in an autoclave, by ethylene oxide, or by another sterilization system. In any case, the sterilization system **10** is a predefined location where devices are placed for a specific reason. The proposed idea was to use the sterilization system **10** to sterilize and recharge the patient-tracking devices. The method eliminated the step of placing the devices in the cabinet after sterilization. Rather, the devices could be recharged while they were being sterilized.

[**0046**] Another implementation of the RF power portal can be constructed in a loading dock **28**. The RF power portal can be used to provide charge to devices as they are exiting or entering the dock to or from delivery trucks **30**. In this case, interference with other equipment may not be a problem, so the RF power portal may not need shielding meaning the RF power portal could be open to allow devices **12** to pass through and not impede normal loading dock **28** functions. It should be noted that the invention has the ability of being transparent to the user by allowing mobile devices **12** to remain mobile rather than requiring them to be stationary for a given period of time in order to be recharged. As an example, the device **12** may be attached to a pallet that is being moved by a forklift **32**. The forklift **32** could simply drive through the RF power portal, which would then supply the device **12** with the required power as shown in FIG. **6**. The device **12** may be but is not limited to an active RFID tag. An active RFID tag is defined as a device **12** with power storage, which uses backscatter, transformer impedance reflection, or a standard antenna to antenna link to communicate with a data receiver **38**. The active RFID tag may be used to measure temperature of a product or may be connected to a cargo container to monitor the contents and other environmental factors such as tampering.

[**0047**] To better illustrate the operation of the RF power portal, consider a typical temperature sensor, which requires one joule of energy to transmit the temperature at a sampling rate of once per hour. If the device **12** will be away from an RF power portal for 12 hours, the device **12** will need to obtain 0.5 joules from the RF power portal for the 12-hour trip. If it is assumed that the device **12** is in the portal area for 60 seconds, the amount of power that must be provided by the portal is 0.5 joules divided by 60 seconds or 8.3 milli-joules per second or 8.3 milli-watts of continuous power. It may not be advantageous for the device **12** to be in the portal area for 60 seconds and therefore the portal area may be expanded to include the trucks **30**, which will be in the portal area for a time far greater than 60 seconds for loading purposes. The expansion of the RF power portal allows the devices **12** to charge not only in the loading dock **28** area but also inside the trucks **30**. The expanded RF power portal can be seen in FIG. **7**.

[**0048**] In a similar example shown in FIG. **8**, an active RFID tag or other sensing device **12** could obtain enough charge at a first loading dock **28** to ensure its operation for the duration of the travel to a second loading dock **28** where it would again receive power. In this application, charging the device **12** at discrete locations ensures that the device **12** can function without wired battery recharging or battery replacement throughout the lifetime or duration of the device **12**. It should be noted that the device **12** may have a power storage device **12** other than a battery such as, but not limited to, a capacitor.

[**0049**] The concept of an RF power portal can be expanded without limit to include greater than two areas. The increased number of RF power portals will decrease the demands on each individual RF power portal by decreasing the distance between portals thereby decreasing the amount of power that each area must supply to the device **12** for its travel between RF power portals.

[**0050**] For another example, a plurality of RF power portals may be located in different environments, for example, at a desk, in a car, at home on a kitchen counter, and/or at a coffee shop. A cell phone containing a device **12** may receive power from each or any of the RF power portals as the cell phone is within each power portal's coverage area. For example, a user may have the cell phone at work. The cell phone receives power from the power portal at the desk when in the coverage area for the transmitter of the desk power portal. When the user then enters his car, the cell phone would receive power from the power portal in the car. When the user places his cell phone on the kitchen counter, the cell phone would receive power from the power portal on the kitchen counter. When the user goes to the coffee shop, the cell phone would receive power from the power portal at the coffee shop. The cell phone would collect power from each power portal which would provide power to the cell phone during travel between the power portals.

[**0051**] Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

The invention claimed is:

1. A system for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current comprising:

a first portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the first portal; and

a second portal separate and apart from the first portal with a gap between the first portal and the second portal, the second portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current after the device has passed through the first portal and the gap and is in the second portal.

2. A system as described in claim 1 wherein each portal is defined by a minimum field strength.

3. A system as described in claim 1 wherein each portal has a wireless energy transmitter.

4. A system as described in claim 3 wherein the wireless energy transmitters produce pulses of energy.

5. A system as described in claim 1 including a third portal separate and apart from the first portal and the second portal with a second gap between the third portal and the second portal, the third portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current after the device has passed through the second portal and the second gap and is in the third portal.

6. A system as described in claim 5 wherein each portal has a wireless energy transmitter.

7. A method for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current comprising the steps of:

moving the device into a first portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the first portal;

converting the wireless energy transmitted in the first portal by the energy harvester of the mobile device into current when the device is in the first portal;

moving the device from the first portal to a second portal separate and apart from the first portal through a gap between the first portal and the second portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the second portal; and

converting the wireless energy transmitted in the second portal by the energy harvester of the mobile device into current when the device is in the second portal.

8. A method as described in claim 7 including the step of moving the device from the second portal to a third portal separate and apart from the first portal and the second portal through a second gap between the second portal and the third portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the third portal.

9. A method as described in claim 7 wherein the moving the device into the first portal includes the step of moving the device into the first portal which is at a loading dock.

10. A method for powering a mobile device having an energy harvester which receives wireless energy and converts the energy into current comprising the steps of:

moving the device into a portal in which wireless energy is transmitted for the energy harvester of the mobile device to receive and convert it into current when the device is in the portal;

converting the wireless energy transmitted in the portal by the energy harvester of the mobile device into current when the device is in the portal;

moving the device out of the portal;

moving the device back into the portal for the energy harvester of the mobile device to receive and convert the energy into current when the device is in the portal; and

converting the wireless energy transmitted in the portal by the energy harvester of the mobile device into current when the device is back in the portal.

11. A method as described in claim 10 wherein the portal is defined by a minimum field strength.

12. A method as described in claim 10 wherein the portal has a wireless energy transmitter.

13. A method as described in claim 12 wherein the wireless energy transmitter produces pulses of energy.

14. A method as described in claim 13 wherein the moving the device into the portal includes the step of moving the device into the portal which is at a loading dock.

15. A method as described in claim 9 wherein the device is an RFID tag.

16. A method as described in claim 15 including the step of communicating data from the RFID tag to a data receiver.

17. A method as described in claim 7 including the step of communicating with the device with a communication transceiver.

18. A method as described in claim 17 wherein the communication transceiver is co-located with a wireless energy transmitter.

19. A method as described in claim 10 wherein the moving the device into the portal step includes the step of moving the device into the portal which is at a recharging cabinet.

20. A method as described in claim 19 including the step of eliminating interference with other equipment and protecting humans from the energy with shielding in the recharging cabinet.

21. A method as described in claim 10 including the step of communicating with the device with a communication transceiver.

22. A method as described in claim 21 wherein the communication transceiver is co-located with the energy transmitter.

23. A method as described in claim 12 wherein the portal has a plurality of wireless energy transmitters.

24. An apparatus as described in claim 6 wherein the portal has a plurality of wireless energy transmitters.

25. A method as described in claim 6 including the step of charging a charge storage element in the device.

26. A method as described in claim 10 including the step of charging a charge storage element in the device.

27. A system as described in claim 1 wherein the device includes a charge storage element in the device in communication with the energy harvester to receive the current from the harvester to charge the storage element.

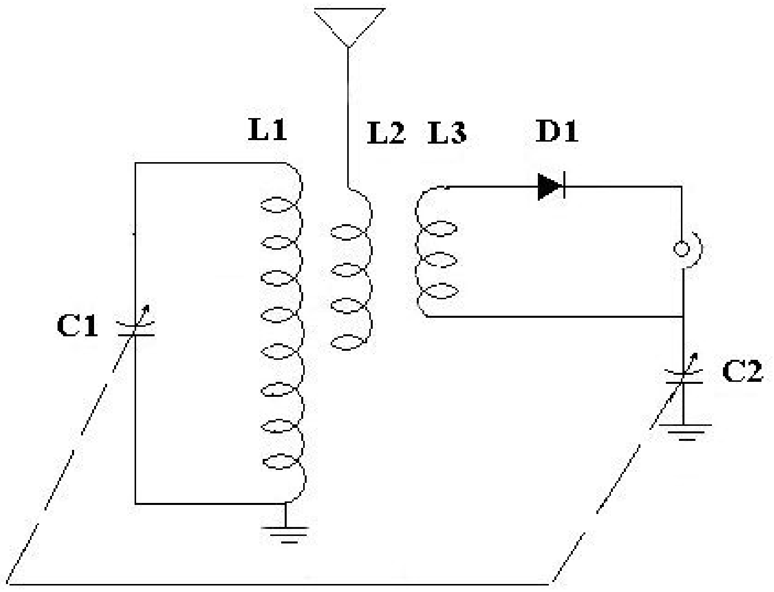
Crazy Crystal Set

copyright © 2006 by Larry J Solomon

Experimenting with various circuits, and using the Mystery set as a starting base, I wanted to create a receiver with a double-ganged (oder *döppelganger*) capacitor. This turned out to be not as simple as it first seemed. Simply replacing the two variables with a döppelganger made the set untunable, because the two rotors are connected together and are inseparable. So, I began tinkering with the circuitry, trying this and that. The circuit that worked best seemed impossible. Indeed, some who see this will probably proclaim it to be impossible. To the contrary, it is not only possible, but a fine performer.

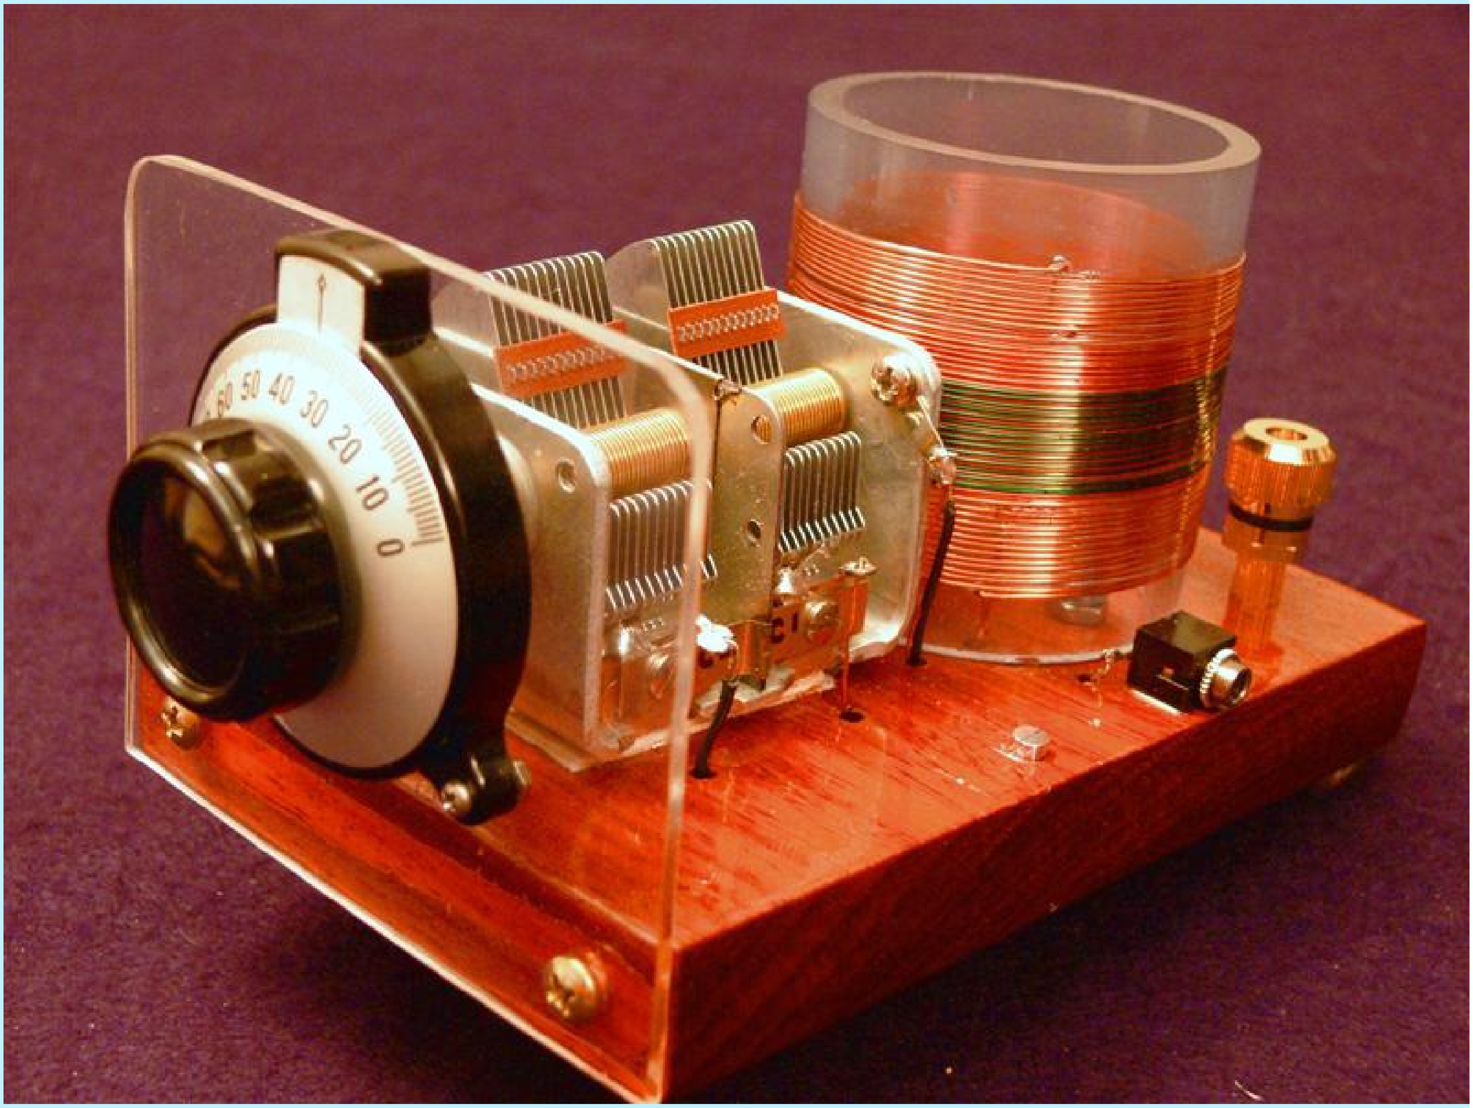


L1 - 45 turns 24 gauge magnet wire
L2 - 15 turns 26 gauge magnet wire wound on top of L1 and L3 separated by a layer of varnish
L3 - 25 turns 30 gauge magnet wire wound parallel to L1 after 12th turn of L1
C1-C2 500uF double-ganged air variable capacitor
D1 - 1N34 diode or rock crystal
Coil form 2.5 inch diameter x 2.5 inch long

I

I call this weird circuit the **Crazy Crystal Set**. Notice that there is not a single resistor or fixed capacitor. The astonishing thing is the dead end coil, L2, connected to an antenna but going nowhere! I have never seen such a circuit in print before. However, it works beautifully! Here are some of my photos.

<>



This shot shows the simplicity of the set, the vernier dial, coil, and capacitor.Most of the wiring is under the chassis. The phone jack can be used for high impedance phones or for audio output to magnetic phono (low level) input on a stereo amplifier. Sensitivity and selectivity are both good.

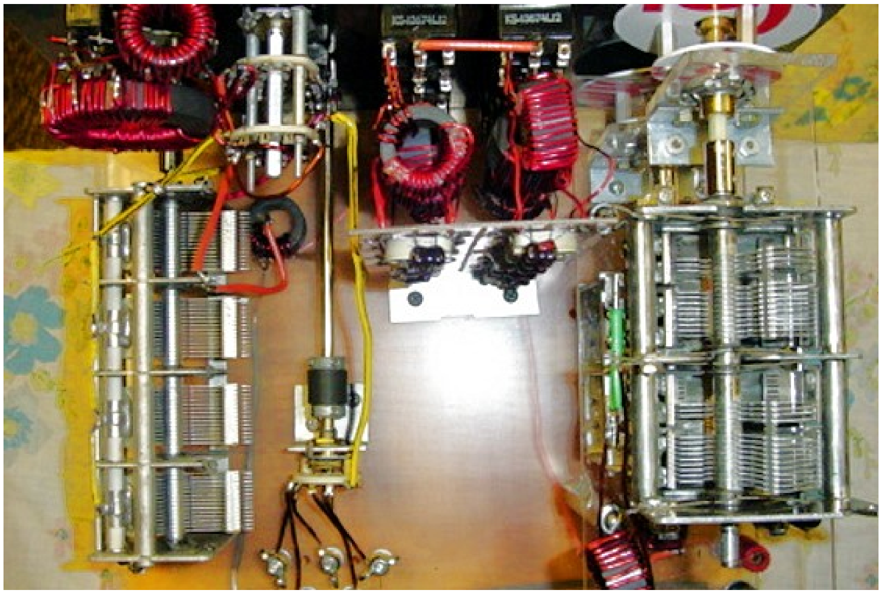
Matching The Antenna

Many crystal sets use a variable capacitor in series with the antenna and the top of the antenna tank circuit (parallel coil/ capacitor) or between the ground and the antenna tank circuit. However, that is not the only way!

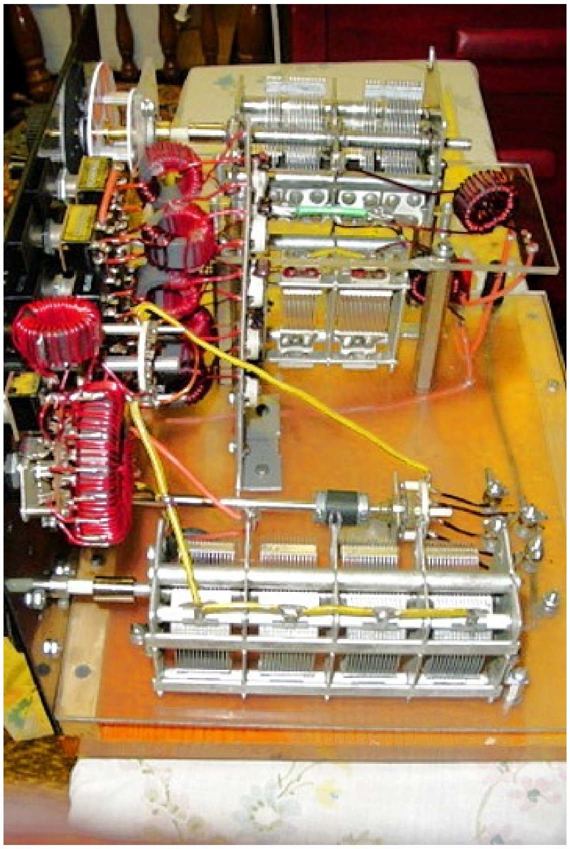
In the following pages we will look at some other approaches.

Lem's Antenna Matching Unit

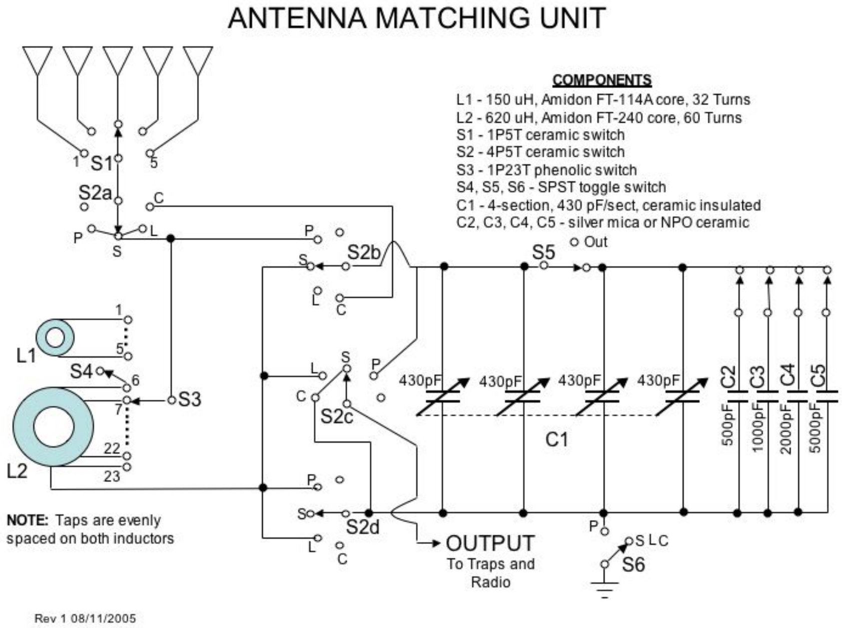
Front of the unit. Lem used a black plastic clipboard from WalMart for the front panel.



Top view showing lots of FT114A-61 cores.



Right view showing the variable traps and series connected 8:1 verniers for an effective ratio of 64:1.



ANTENNA MATCHING UNIT

COMPONENTS
L1 - 150 uH, Amidon FT-114A core, 32 Turns
L2 - 620 uH, Amidon FT-240 core, 60 Turns
S1 - 1P5T ceramic switch
S2 - 4P5T ceramic switch
S3 - 1P23T phenolic switch
S4, S5, S6 - SPST toggle switch
C1 - 4-section, 430 pF/sect, ceramic insulated
C2, C3, C4, C5 - silver mica or NPO ceramic

NOTE: Taps are evenly spaced on both inductors

CRYSTAL SETS 4: A CRYSTAL SET BUILT BY KENNETH RANKIN

MDS975.co.uk reader Roddie Rankin kindly sent in the details of a crystal set built by his son Kenneth for a school project which won him great praise and merit. The crystal set is so nicely made and the project so well written that I thought it deserved a special page of its own.

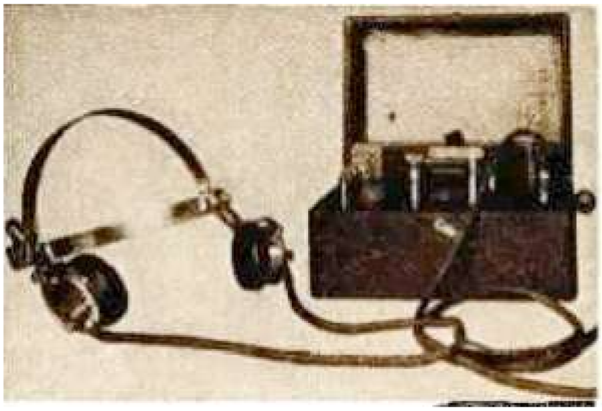
1 - WHAT IS A CRYSTAL SET?

Perhaps you think, like I did, that a crystal set is just a collection of lovely stones. In fact a crystal set is a very early, simple domestic radio. The photograph above shows the crystal set I built.

The crystal set does not have a battery. It runs completely from the radio waves it picks up in the air. It is absolutely free to run!

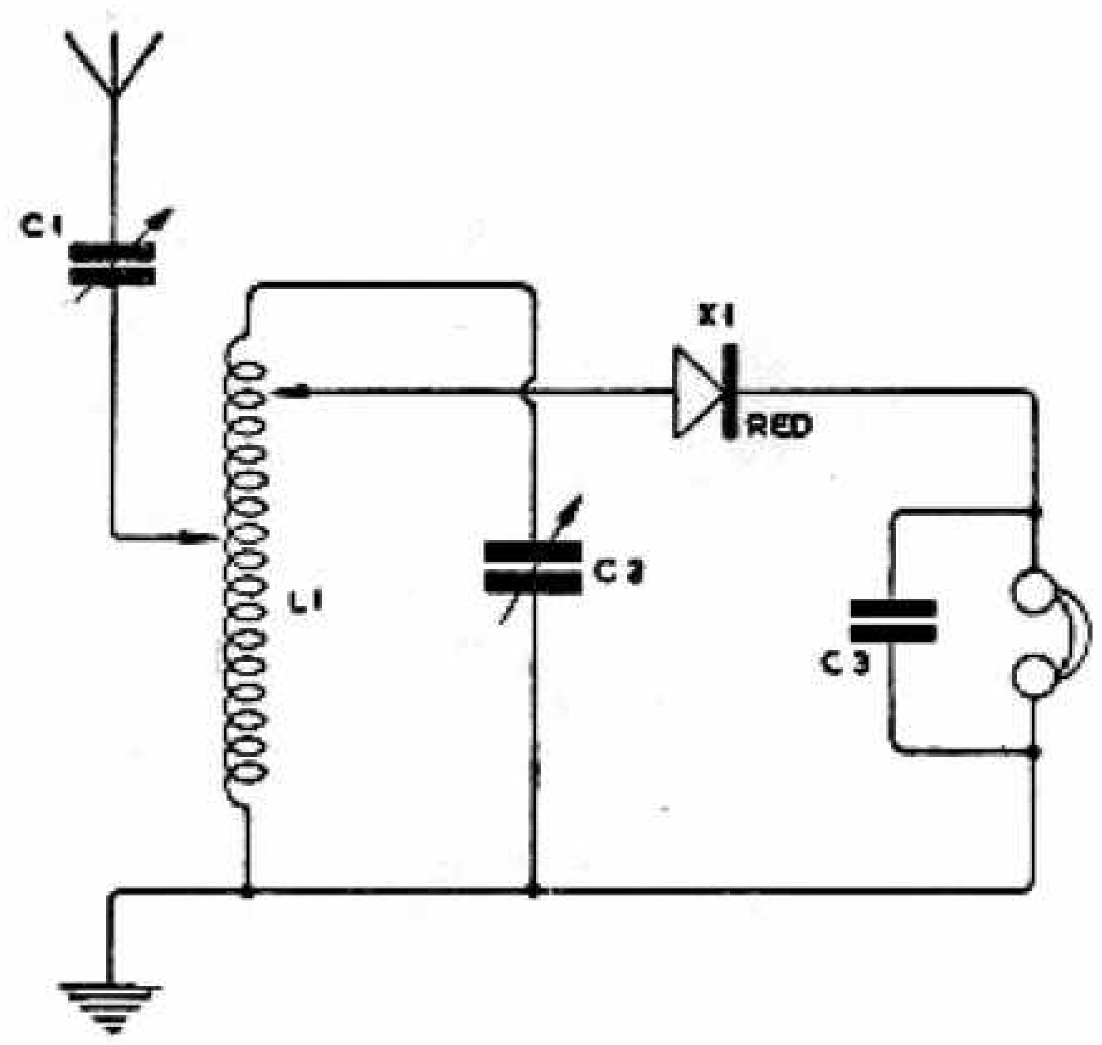
Please read on to find out more about this exciting invention!



The birth of domestic radio: A deluxe crystal set produced by Marconi for the reception of programmes from the first of the BBC's radio stations, 2LO in London.
[from Pageant Of The Century - Odhams Press]

2 - HOW A CRYSTAL SET WORKS

The diagram below shows the circuit diagram of the crystal set I have built. It consists of a coil (L1), a tuning capacitor (C2), a diode (X1), an aerial, a crystal earpiece and an earth. (Capacitors C1 and C3 are not essential.)



Circuit Diagram Of The Crystal Set

First the aerial picks up radio waves from radio stations all over the world. Then the required station needs to be selected, this is called tuning, and this is achieved with a Tuned Circuit. The Tuned Circuit in the crystal set consists of two items; a component called a variable capacitor and a coil of wire.

By adjusting the value of the capacitor and coil tuning is achieved. The coil taking unwanted signals of low frequency straight through to the earth, which gets rid of them, while the capacitor takes unwanted signals of high frequency straight through to the earth. The remaining signal, in between the high frequency and low frequency signals, is the signal of the required station which is not passed to earth by either the coil or the capacitor. This is the frequency to which the set is now tuned in.

You normally change the frequency to which a set is tuned in to by turning the knob on the tuning capacitor, thus receiving different stations by varying the capacitance of the variable capacitor. The number of turns on the coil can also be changed [called varying the inductance of the coil] and this will give different tuning ranges. A larger number of turns provided longer wavelengths [lower frequencies], while a smaller number of turns of wire provides shorter wavelengths [higher frequencies].

[It is also worth noting that the inductance of a coil can be increased by inserting a component called a Ferrite Rod into the centre of the coil.]

Once tuned into the required station this remaining signal goes to earth by travelling through the diode and earpiece. The diode takes the sound signal out of the radio signal [called demodulation], and passes it to the earpiece. The sound signal travels through the crystal in the earpiece which vibrates the air in the earpiece giving us the sound of the radio station to which you are tuned.

3 - THE HISTORY OF THE CRYSTAL SET

The history of crystal sets begins with the first broadcast stations being opened. This happened in England in 1922. The simplest form of receiver for these broadcasts was the crystal set.

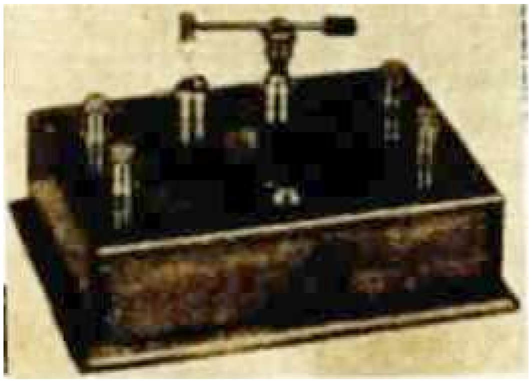
In those early sets they had "cat’s whiskers" instead of diodes. A cat’s whisker was a fine piece of wire which was adjusted to make a suitable contact with a crystal. The crystal would be made of a substance such as coke or galena. An example from 1923 is shown in the picture below. Notice how well made these instruments were.

There were several limitations to the crystal set: it needed a big aerial, an earth connection, the clumsy cat’s whisker, and the weak signal could only be listened to by one person at a time with headphones. Very quickly the crystal set began to be replaced by valve radios with loudspeakers, powered by battery (see the picture from 1923).

In World War II, crystal sets were used by prisoners of war in prison camps to listen to news from home. As they were often badly treated it was hard to get all the right parts to build the set.

By this time crystal sets were no longer used in the home. Instead radios like the attractive 1937 model in the picture were being used.

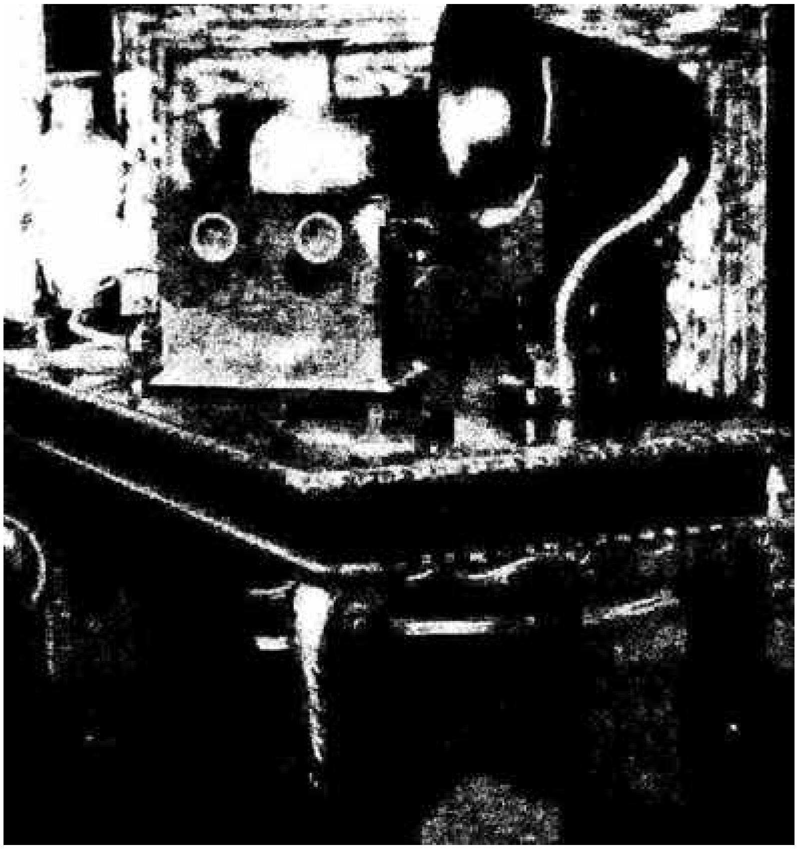
Nowadays people only use crystal sets as a hobby. There are various different kits available on the market (see websites in the references below).



Photograph Of A Crystal Set From 1923

[from Pageant Of The Century - Odhams Press]

Crystal sets were primitive instruments used for 'listening in', and were fitted with the now famous cats whisker. Listening was done though a pair of headphones which meant that only one person could listen at a time.



Photograph Of a 1923 Radio

[from Pageant Of The Century - Odhams Press]

Later valve amplification could be added to radios which allowed them to power a loudspeaker so that everyone in a room could listen in.

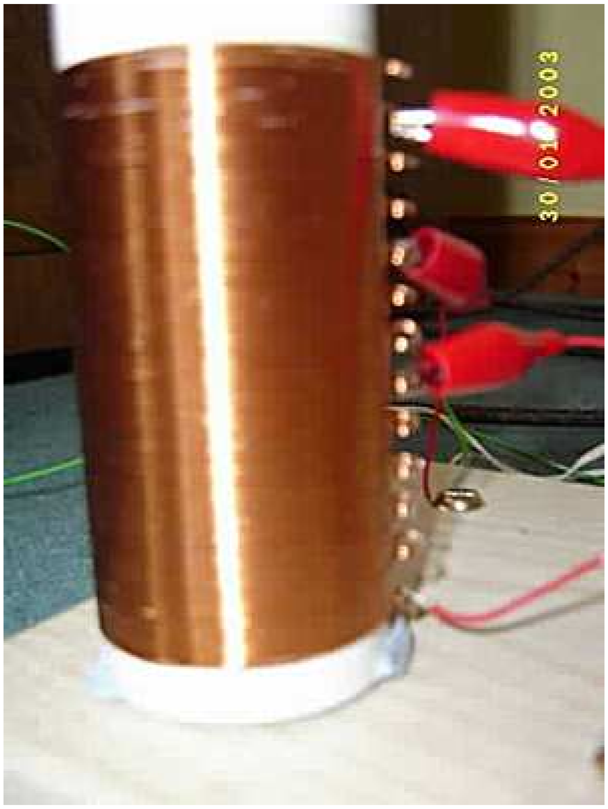
4 - HOW I BUILT MY CRYSTAL SET

The crystal set is a fun and easy thing to build.

The first thing I had to do was put up an aerial and earth. For the aerial I drilled a hole in the ceiling and fed wire through the hole. Then I went into the attic and took the wire to the other end of the attic, fastening it to rafters as I went. When I got to the other side I fed the wire out of an air vent to the outside of the house. I then went outside tied wire to a nearby tree and joined it up to the wire coming out of the air vent. This gave me an aerial of about 25 metres.

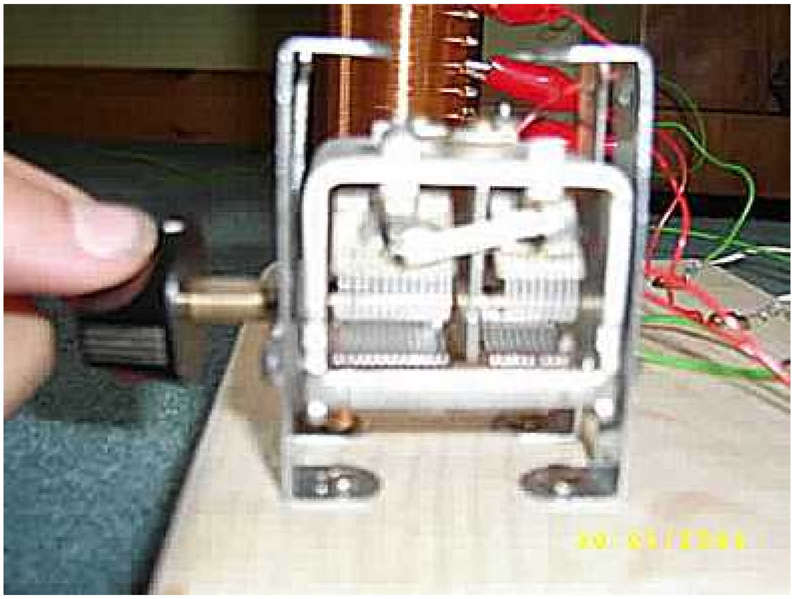
Next the earth. For this I drilled another hole in the ceiling and fed another wire through and out of an air vent at the other side of the house (see previous paragraph). I attached this wire to the metal frame of my swing. This is a good earth because its poles stick deep into the ground.

The coil used enamelled copper wire wound on to a piece of plastic pipe with a diameter of 5 cm. There were 120 turns of wire. Every 10 turns I made a loop on which a crocodile clip could be fixed. See the picture below:



30/01/2003

Photograph Of The Coil Showing The Tapping Points & Crocodile Clips



The Tuning Capacitor - Being Carefully Adjusted

For the crystal set itself, I first had to plan what I would be using and where the pieces would be placed (see picture and the plan drawing). I was using the circuit shown above. I built the crystal set on a wooden board about 20cm by 15cm. I drilled 4 holes 4cm apart. I put screws with cup washers in each hole and fastened the wires of the parts of the crystal set and the aerial and earth wires under the cup washers. I fastened the capacitor to the board using Meccano brackets and screws. The coil was fixed to the board using glue. The earpiece plugged into a socket which was fastened to the board using a thunderbolt shaped piece of Meccano.

5 - THE RESULTS I OBTAINED

At first all I could hear was a foreign station. But then, I tried late at night and could sometimes hear a station from Florida in English! By tuning the capacitor and moving the crocodile clips up and down the coil I managed to receive a few foreign stations on Short Wave. What I really wanted was to tune in to Medium Wave. I wanted to receive English stations like Radio Scotland and music stations. I tried everything including a longer aerial and using different parts but to no avail. I came to the conclusion that I could not get a strong enough Medium Wave signal in Northerly area of Scotland where we live.

Here is a picture of me operating my crystal set:

7 - QUIZ QUESTIONS

CRYSTAL SET QUIZ QUESTIONS:

1. What is a crystal set?
2. When were the first crystal sets sold?
3. Name 3 essential parts for a crystal set.
4. What does the earth do?
5. Does the coil pass signals of low frequency or high frequency?
6. How far apart were the screws on my crystal set?
7. What happened when I made the aerial longer?
8. What is this an anagram of: i a c c p r o t a?

(ANSWERS ARE FURTHER DOWN THIS PAGE)

PARTS THAT ARE REQUIRED

1	Wooden Base Panel
1	Coil Former 5cm dia. UPVC Pipe
1	Tuning Capacitor approx 500pF Air-Spaced or Solid Dielectric
1	Reel Of Enamelled Copper Wire for coil
1	Germanium Diode eg OA47 and IN34 which are especially suitable or other alternatives such as OA81, OA90 OA91, 1N94 etc
1	Crystal Earphone
1	47 k Ohm Resistor across earphone
6	½ inch No. 6 Brass Screws and Screw Cups
1	3.5mm mono Jack Socket
	Mounting Hardware (Meccano) for coil, capacitor and jack socket
	PVC covered wire for aerial and earth

A Superb RGD Valve Radio from 1937 - carefully restored in 1994 by Roddie Rankin

With thanks to Kenneth and Roddie Rankin for sending in this excellent article and photographs!

Crystal Sets Part 5 >

QUIZ ANSWERS

1. The first kind of radio
2. 1922.
3. Coil, diode, capacitor, earpiece, aerial, earth.
4. Gets rid of signals you don’t want.
5. Low.
6. 4 cm.
7. It did not make much difference.
8. Capacitor.

No AM radio stations or transmitters in your locality or country?

Spitfire
AM Transmitter

Has your local medium wave broadcast station closed or been moved to VHF/FM or Digital? Don't worry. You can still build and experiment with crystal sets and TRF radios by also buying or even building a simple low power AM transmitter. So, not only can you use your crystal sets but you can also run your own radio station that can be heard in and around your home - playing the music or programmes that you want to hear!

SSTRAN AMT3000 : Superb high fidelity medium wave AM transmitter kits from SSTRAN. Versions available for 10kHz spacing in the Americas (AMT3000 or AMT3000-SM) and 9kHz spacing in Europe and other areas (AMT3000-9 and AMT3000-9SM). Superb audio quality and a great and well designed little kit to build: http://www.sstran.com/pages/products.html

Jeffrey La Favre August 1, 2015

Understanding and Operating Your Crystal Radio

Your crystal radio receiver is designed to tune stations on the AM broadcast band (radio frequencies of 540 to 1610 kHz). You will be limited in the number of stations you can hear when operating the radio without amplification. Keep in mind that a crystal radio operates ONLY on the power received from the radio station transmitter. Therefore, your ability to hear a station will depend to a great extent on the distance from the radio transmitter to your house and the amount of power the station uses to broadcast their signal. Another important factor will be the antenna you use with your radio.

Most of our club members live in Geauga County. As far as I know, there is no radio station broadcasting on the AM band in our county (at least not a powerful station). From my home in Chesterland, the strongest station tuned on my crystal radio is WTAM. This station broadcasts with 50,000 watts of power on a frequency of 1100 kHz. The radio transmitter is located at 8200 Snowville Road, Brecksville, Ohio. The distance from the transmitter to Chesterland is about 23 miles (21 miles to Auburn Twp and 31 miles to Chardon). Figure 1 is an aerial view of the WTAM transmitting antenna, which is 480 feet tall.

Figure 1 WTAM transmitting antenna

As radio waves travel away from the transmitter, the power density of the radio energy varies inversely with the square of the distance. What does that mean? We can write this as a proportion:

$$power\ density \propto \frac{1}{distance^2}$$

Let me give some examples. The power density of a radio wave at a distance of 10 miles from the transmitter is:

$$power\ density \propto \frac{1}{10 \times 10} = \frac{1}{100} = 0.01$$

The power density at 20 miles is:

$$power\ density \propto \frac{1}{20 \times 20} = \frac{1}{400} = 0.0025$$

Therefore, the power density at 20 miles is 1/4th the power density at a distance of 10 miles. At a distance of 40 miles, the power density will be 1/16th the power density at 10 miles. All other things being equal, if your crystal radio is located 40 miles from the transmitter, the signal strength delivered to the radio will be 1/16th what it would be if located 10 miles from the transmitter. This is why you will have a better chance of hearing a station, the closer you are to its transmitter. Of course the amount of power used in transmitting makes a difference. If two stations are the same distance away, but one transmits with 1,000 watts of power and another transmits with 50,000 watts, the 50,000 watt station will be considerably louder than the one with 1,000 watts.

Antenna for the Crystal Radio

The antenna you connect to your crystal radio will determine to a great extent the number of stations you can hear. It is doubtful that an indoor antenna will be sufficient unless you live within a few miles of an AM radio transmitter. Provided that you have permission from your parents, you can install an outdoor antenna. You should ask your parents for assistance in erecting the antenna. This can be a temporary antenna, put up only when you are using the radio, or a more permanent installation. Again, you should ask your parents which kind of installation they will allow. Some people think that antennas are not attractive and you must keep this in mind.

The antenna that I use for my crystal radio is of the long wire type (14 gauge, stranded and insulated). It is permanently installed. I drilled a hole through the window frame to allow the antenna wire to exit from the GEAR workshop to the outside. I installed a hook on the edge of the roof and with an insulator, attached the wire antenna. The wire length from window to the edge of the roof is 11 feet. Then the wire runs to a tree 50 feet from the roof. The attachment to the tree is 18 feet above the ground. The wire then runs to another tree 61 feet from the first tree and also 18 feet above the ground. At the second tree the wire goes through a pulley and then down to the ground where it is attached to a weight. The total length of the antenna wire, from the window to the end is 140 feet (you will also need additional length inside the house to reach the radio). The pulley is used as part of the antenna tensioning system. When the wind moves the tree branches, the wire moves through the pulley to prevent breakage of the wire. The weight at the end of the wire provides the tensioning of the antenna so that it does not dip excessively toward the ground between its supports. This antenna works well and I can hear four or five stations during the day.

When you work 18 feet above the ground, there is danger of a serious or fatal injury from a fall. If you want to erect an antenna like the one I have described, **DO NOT ATTEMPT THIS ON YOUR OWN. PLEASE HAVE YOUR PARENTS HELP YOU**. I used a ladder to attach the antenna wire to the trees. This kind of work can be very dangerous and you must use proper safety procedures. The job takes a minimum of two people, one to hold the ladder while the other person climbs the ladder. The ladder should be secured with ropes so that it will not slip off the tree. It is also a good idea to use a safety harness that connects the climber to the ladder in case they slip on a ladder rung.

A safer procedure, although possibly more frustrating, is to throw a light line over a tree branch from the ground. Attach a weight to the end of a string and attempt to throw the weight over a branch. If that does not work you might try using a slingshot. It would be a good idea to wear a hard hat or bicycle helmet while doing this in case the thrown weight comes back down on your head! If you have a very long pole, you might use that as well to hoist the wire over a branch. These methods are preferred over the ladder since they are safer. After you are successful in getting a string line over a tree branch, connect the string to your antenna wire and pull the string to hoist the antenna wire in place.

Ground Connection for the Crystal Radio

In addition to the antenna, a connection to ground is required. The ground connection is actually part of the antenna system. For the antenna I have described, I used a grounding rod, which you can find in the electrical department at a hardware store. The rod is 8 feet long and all but a few inches are driven into the ground with a sledge hammer. Make sure there are no pipes or underground electrical wires in the area where you install the grounding rod. It is best to install the rod near where the antenna wire exits the house. The rod is copper-clad steel. A special bronze clamp is used to attach a ground wire to the rod. The other end of this ground wire is connected to the ground connection (black wire) of the antenna coil of the radio. The grounding rod must be in moist soil to work well. Of course it is difficult to know how moist your soil is 8 feet below the surface. But if your antenna does not seem to be working very well, you may need to water the soil around the grounding rod.

If you are not sure you will use your radio very much, you may decide to erect a shorter outdoor antenna. I erected a temporary long wire antenna, 11 feet from window to edge of roof, 50 feet to a tree branch that was 7 feet off the ground, then ran the wire to the ground and tied to a weight (total of 68 feet of wire from the window to the end of the wire). For this antenna I did not use a grounding rod. Instead, I connected the ground wire of the antenna coil to the ground system of the house electrical wiring. This can be done by connecting a wire to the screw of a faceplate for an electrical receptacle – see Figure 2 (**DO NOT PUSH THE WIRE INTO ONE OF THE RECEPTICLE SLOTS AS THIS COULD RESULT IN A FATAL ELECTRIC SHOCK**).

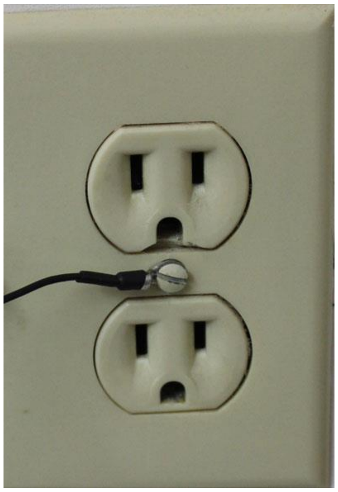

Figure 2 ground wire connected to faceplate

Using the shorter antenna and ground to faceplate, I could only hear station WTAM 1100. After you have completed the audio amplifier for your crystal radio, you will be able to hear more stations with the shorter antenna. However, if you have an interest in hearing distant stations, the longer antenna with grounding rod will be better.

When there is a chance of an electrical storm in your area, it is advisable to disconnect your antenna at a location outside your house. While lighting strikes on an antenna like yours are rare, it is better to be safe and prevent the very high current and voltage from entering your house. It is best if your exterior antenna is connected to ground outside the house when not in use.

Calibrating the Tuning Dial

The knob connected to the variable capacitor of the radio has a white pointing line to indicate the position of the variable capacitor. The position of the variable capacitor determines the radio frequency tuned (the station). However, the front face of the radio does not have any markings to indicate the frequencies for various positions of the knob. Mr. La Favre will help you mark the face of the radio at intervals of frequency. To do this we will use a signal generator. The signal generator will be connected to a coil that will substitute for the antenna coil. The signal generator can be adjusted to any radio frequency desired. In addition, the radio frequency can be modulated (AM - amplitude modulation) with an audio frequency, which you can hear as a tone in the radio earphone. We will start by adjusting the signal generator to a radio frequency of 600 kHz, modulated with an audio frequency of 400 Hz (400 Hz is a tone just a bit lower than the musical note A above middle C – that A is 440 Hz). The coil attached to the signal generator is placed next to the tuning coil of the radio. Then the tuning knob of the radio is adjusted until the 400 Hz tone is heard clearly in the radio earphone. The knob is adjusted to the position where the tone is heard with the highest volume. At that point a felt-tipped pen is used to place a mark on the front plate of the radio to match the position of the white line of the tuning knob. Then that line is labeled with the number 600 (600 kHz). We will continue by adjusting the signal generator in increments of 100 kHz, marking each knob position for each frequency. When finished, you will have marks on the face of the radio for 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400, 1500 and 1600 kHz. These marks will be helpful in adjusting the variable capacitor to tune a specific station.

Functions of the Various Components of the Crystal Radio

The most important reason for completing the Crystal Radio project is to learn how a radio works. Of course I also hope you will enjoy using your radio. To begin, let us take a look at the schematic for the radio provided below.

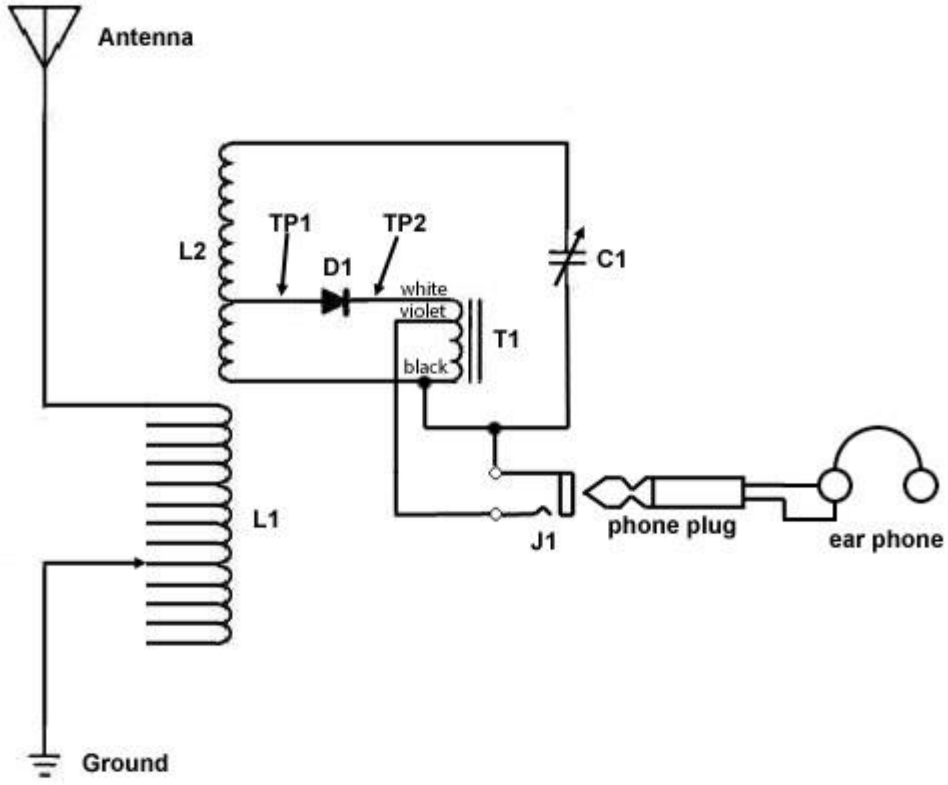

Figure 3 schematic of the Crystal Radio

L1 is the antenna coil and L2 is the tuning coil. The antenna coil has 12 taps. The ground wire is terminated with an alligator clip, which is used to connect to one of the taps. After tuning a specific station with the variable capacitor, C1, the ground wire is connected to the tap of coil L1 which gives the loudest signal as heard in the earphone. By selecting the best tap on coil L1, you are actually tuning the antenna to *resonate* at the tuned frequency. An antenna that is tuned to a specific radio frequency will deliver the strongest signal to the radio. When you adjust the variable capacitor to tune another station, you may need to adjust the tap connection on L1, especially if the new station tuned is of a significantly different frequency than the previously tuned station. Higher frequency stations will require connection to a tap closer to the antenna end of the coil. As you tune stations of lower frequency, you will need to adjust the tap connection to a tap further from the antenna end of the coil. In other words, a station of lower frequency will require the signal to travel through more coil turns than one of higher frequency. The exact tap to use will also depend on the length of your antenna.

Therefore, it is not possible for me to tell you which tap to use for a specific station. You will need to establish this by trial and error. If you are not able to find a tap on the coil that provides a stronger signal than other taps, then it is likely that your antenna is too short to tune to resonance. Nevertheless, this will not prevent you from hearing stronger stations.

Figure 4 below is a photo of the assembled radio. The green wire labeled A is the antenna wire and the black wire labeled B is the ground wire which connects to the grounding rod just outside the window of the GEAR workshop. D is the antenna coil (L1 in schematic). C is the alligator clip, attached to one of the taps of the coil. The red wire of the antenna coil connects to the antenna wire and the black wire connects to the ground wire. After making these connections, and placing the antenna coil (D) near the tuning coil (E), your radio is ready for use.

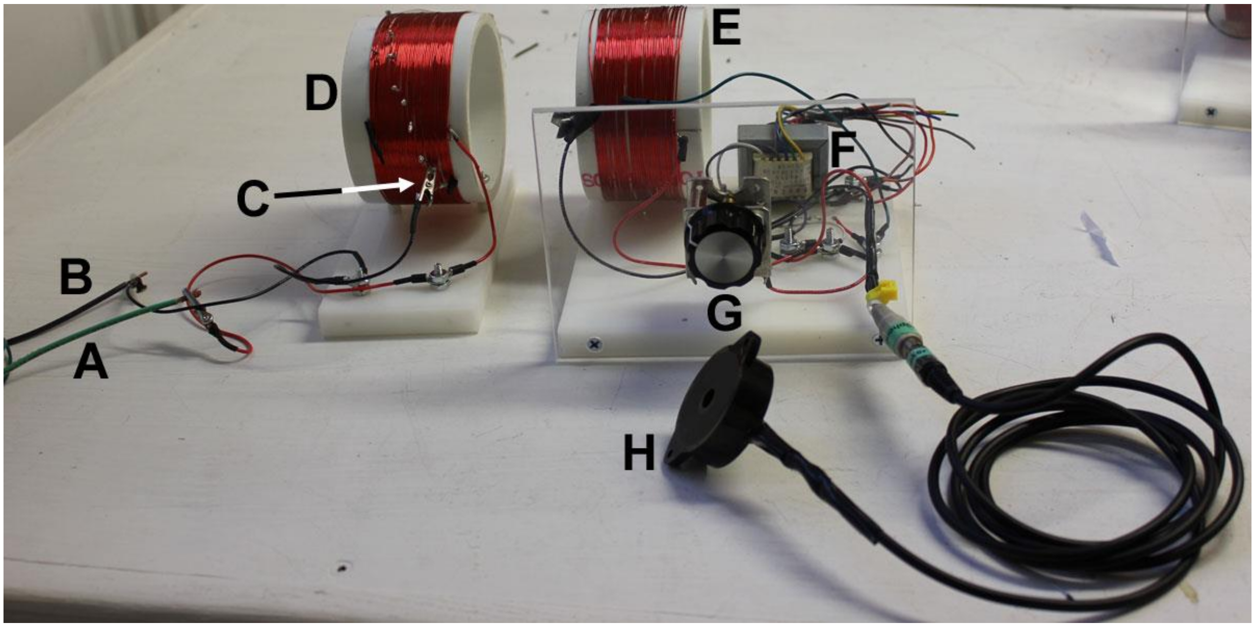

Figure 4 assembled crystal radio

F is the audio transformer, which is labeled as T1 in the schematic of Figure 3. The audio transformer is used to match the impedance of the earphone (H). G is the knob attached to the variable capacitor.

The radio signal present in the antenna coil (D) is transferred to the tuning coil (E) by the magnetic field generated by the antenna coil. When current flows through a coil, a magnetic field develops around the coil. If another coil is placed near that coil, then the second coil is also immersed in the magnetic field created by the first coil. This is the means for transferring the radio signal from the antenna coil to the tuning coil.

The transfer of the signal between the coils can only occur if the current flowing in the antenna coil is alternating current. As it happens, the current established in the antenna coil is alternating current. When an antenna captures radio waves, the radio waves are converted to an alternating current in the antenna circuit, which includes the antenna coil. As the current flows back and forth through the antenna coil, the magnetic field builds and then collapses around the antenna coil. It is the changing magnetic field which is required to transfer the electrical energy from the antenna coil to the tuning coil.

If the current flowing in the antenna coil was a constant direct current, there would be no transfer of electrical energy to the tuning coil.

The antenna coil and tuning coil together constitute a type of transformer. Transformers play important roles in electrical systems. The usual function of a transformer is conversion of voltage from one level to another. There is a transformer mounted to the electric pole near our house. It converts the high voltage (several thousand volts) of the electric line down to 240/120 volts for service to our house. In the case of our radio, we are not so much interested in converting the voltage of the signal in our antenna circuit as just transferring that signal to the tuning coil. We could just use one coil and connect the antenna, ground and variable capacitor to that coil. However, better results are obtained by using separate coils to tune the antenna and then transfer that tuned signal to the tuning coil via a magnetic field.

The antenna coil and tuning coil are mounted on separate bases so that you can adjust the distance between the coils. There will be a specific distance between the coils that results in the strongest signal received in the tuning coil and this may vary with the radio frequency tuned. The optimum spacing is not necessarily the closest spacing. As part of the process of tuning a station, you should adjust the space between the coils for maximum loudness heard in the earphone. In any case, the distance between the coils for best transfer of signal will be similar to that seen in Figure 4. For example, if you place the coils 12 inches apart, there will be little signal transfer.

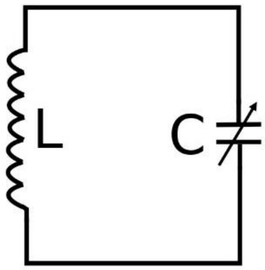

Figure 5 simple LC circuit with coil and variable capacitor

The variable capacitor C1 works together with the tuning coil (L2 schematic or E in photo) to tune a specific radio frequency. The tuning coil has a fixed amount of *inductance* and it is the adjustment in *capacitance* of C1 that allows tuning of different frequencies. Figure 5 shows a simplified version of the LC circuit of the crystal radio. The actual circuit for our radio contains a tap on the coil for diode D1 as well as other connections. But let us concentrate only on the coil L and capacitor C. In a certain respect the circuit of Figure 5 is an open circuit because current cannot pass through capacitor C. To be more precise, the circuit is open as far as direct current is concerned. However, we can consider the circuit closed in respect of alternating current. Capacitors behave in a fashion that allows current to flow temporarily in a circuit as the capacitor charges. With alternating current, the current flows for a short period only in one direction, especially at radio frequency rates of alternating current. As the current charges the capacitor, current is allowed to flow in the circuit. Once the capacitor is fully charged, current will no longer flow. What we must keep in mind is that at radio frequencies, current flows in one direction for a very short period of time. Let us take a frequency of 1000 kHz as an example, a frequency in the middle of the AM broadcast band. That frequency is equivalent to 1,000,000 cycles per second. Each cycle results in current flow in one direction followed by current flow in the opposite direction. The duration of flow in one direction is only 1/2,000,000th of a second or 0.5 microseconds. A microsecond is one millionth of a second. That is a very short amount of time. Even so, the electric current in the circuit in Figure 5 could travel around the circuit in much less time than 0.5 microseconds IF we did not include the capacitor and inductor (coil).

In order to tune the circuit for resonance at a specific radio frequency, we want the capacitor to charge and discharge at a rate that equals the frequency. If we removed the inductor (L) from the circuit, the capacitor would charge and discharge much faster than the rate required for tuning the circuit to resonance. By including the inductor, we slow down the rate of current flow, which in turn results in a slower charge and discharge of the capacitor. It is the interesting behavior of an inductor (coil) that we have employed to establish resonance. When voltage is first applied across an inductor, very little current is allowed to flow through the coil. Instead, a magnetic field starts to build around the coil. As time wears on (here we are talking about very little time), more current is allowed to flow through the inductor. The degree of hindrance in current flow by an inductor depends on the amount of inductance of the coil. We measure this in units named Henries, just as capacitance of a capacitor in measured in units of the Farad. An LC circuit containing a coil of a specific value of inductance and a capacitor of a specific value of capacitance will be resonant at a specific radio frequency.

Resonance can be a difficult thing to understand. Let us take the analogy of a child on a swing. As the child swings back and forth, the parent gives a push just as the backward movement stops. The end result of these timed pushes is that the child continues to swing. The swinging of the child is in resonance with the pushes given by the parent and the child will continue to swing indefinitely. Now suppose that the parent delivered the pushes while the child was still moving backward. In this case, with each cycle of the swinging back and forth, the amount of the swing will diminish until it ceases. In this case there is not resonance of the swinging and pushes.

The LC circuit is much the same. At a specific radio frequency, the frequency of resonance, the current flows back and forth in the circuit, timed exactly to match the rate of capacitor charging and discharging (the capacitor is somewhat like the parent pushing). At frequencies other than the resonance frequency, the current flowing back and forth in the circuit does not match the charging and discharging rate of the capacitor. Thus, the electrical energies of the non-resonant frequencies are absorbed in the LC circuit and not passed on to the remaining circuits of the radio. It is by this method that a signal of a specific frequency is allowed to pass through the radio while other frequency are not. If this did not happen, then we would be hearing many radio stations at one time.

Two important characteristics of a radio are **sensitivity** and **selectivity**. Sensitivity is the ability of a radio to deliver a sound that you can hear, derived from a weak radio signal received. Radios other than the crystal type include some type of signal amplification so that stations with weak signals can be heard. Sensitivity can be measured as the minimum signal voltage received that results in audible sound. Crystal radios have poor sensitivity because they rely only on the power received from the tuned radio waves. The efficiency of the radio antenna in capturing energy from the passing radio waves affects the signal strength received by the radio. Since crystal radios do not amplify the signal, it is especially important to use efficient antennas with crystal radios.

Crystal radios are also known in general for poor selectivity, although better designs have better selectivity. It is not uncommon for more than one station to be heard at a particular setting of the variable capacitor due to poor selectivity in the crystal radio. Nevertheless, you will be able to find some stations that you can hear clearly without interference from another station. It just depends on the separation in frequencies of the strong radio stations received at your location. More advanced radios, of the kind you are familiar with, have much better selectivity and usually tune only one station at a time, even when strong stations have frequencies very close to each other. I will not detail the reasons for this any further at this point as the improvements in selectivity require a discussion of circuits not found in crystal radios.

Figure 6 is a portion of the radio schematic showing part of the tuning coil, the detector diode D1 and the audio transformer T1. Two test points are marked on the schematic. We will connect an oscilloscope to these test points so that we can visualize the radio signal at these points in the radio. This will help in understanding the radio.

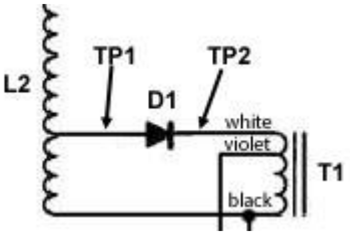

Figure 6 detector schematic of radio

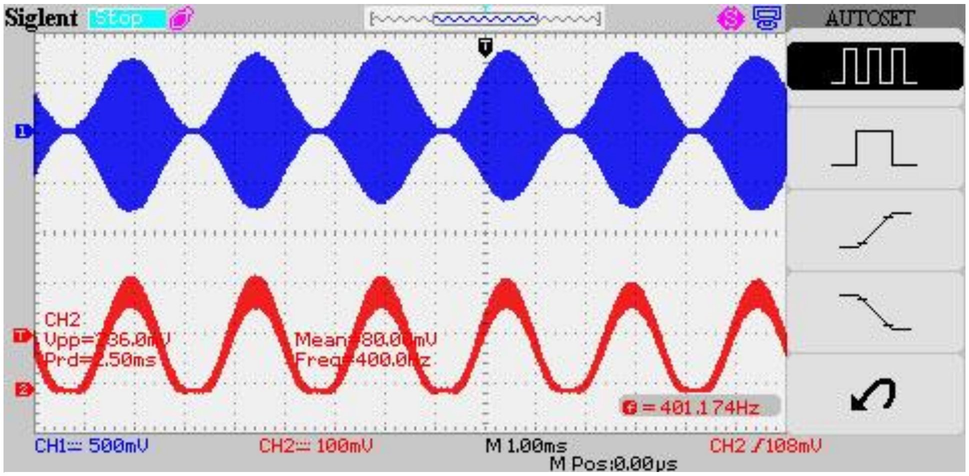
An oscilloscope is an instrument that can be used to visualize rapidly changing electric signals. Figure 7 is the oscilloscope traces at test points one and two (see Figure 6 for locations of test points). A signal generator is connected to the radio providing a radio frequency of 1100 kHz, modulated by an audio frequency of 400 Hz. The blue trace displays the radio frequency at test point one modulated by the audio frequency. In the trace you can only see the waves of the audio signal. The waves of the radio frequency are so numerous that they appear as a solid blue color. It would be necessary to stretch the display to a great extent in the horizontal direction before we could see the individual radio frequency waves in the blue colored trace.



CH2
Vpp=136.0mV
Prd=2.50ms
Mean=80.00mV
Freq=400.0Hz
= 401.174Hz
CH1⎓ 500mV
CH2⎓ 100mV
M 1.00ms
M Pos:0.00μs
CH2 ╱108mV

Figure 7 oscilloscope traces at test point 1 (blue) and test point 2 (red)

The height of the blue radio waves is *modulated* by the audio signal (amplitude modulation or AM). The audio signal is much lower in frequency than the radio frequency (the number of audio modulations are much fewer than the number of radio frequency waves). Notice the blue tab labeled “1” on the left side of the blue trace. That tab marks the position of 0 volts. Any time the wave is above the tab, the voltage will be greater than 0. Any time the wave is below the tab, the voltage will be below 0 (a negative voltage). The radio frequency must have alternating positive and negative voltage in order to force periodic reversal in the direction of current flow (like quickly switching the connections to a battery). Otherwise, the current would not change directions and it would not be alternating current.

You should notice that the red trace, representing the signal at test point two, looks very different. Test point two is on the opposite side of the detector diode from test point one. Also note that for this test the diode connection to the transformer T1 was disconnected. Since the diode blocks current flow in one direction, we should not expect to see positions of negative and positive voltage on the wave trace here. In fact, notice where the 0 volt red tab with the label “2” is located. The bottoms of the red waves are at 0 volts. All positions of the waves are at 0 volts or higher because the diode has rectified the radio signal. We call this *detection*. The diode has converted the alternating current radio signal into a pulsating direct current audio signal. It is the audio signal that we need to apply to the earphone in order to hear the sound. If we were to just apply the radio frequency itself to the earphone we could not hear any sound. Humans are not capable of hearing sound at a frequency higher than 20,000 Hz.

After passing through the detector diode D1, the extracted audio signal passes through the audio transformer. The transformer transfers the audio signal to the earphone where the electric signal is converted into sound waves that you can hear. The transformer performs an important function in matching the *impedance* requirement of the tuning circuit to the impedance requirement of the device used to convert the electric signal to sound. The transformer has many taps that represent different impedances. The tuning circuit is attached to the white and black wires of the transformer, which provide about 40,000 ohms of impedance. The earphone is attached to the violet and black wires of the transformer, which provides 10,000 ohms of impedance. This is the best impedance matching I have found by listening to the signal in the earphone and selecting the loudest sound produced when testing all possible connections on the transformer. If you happen to have another high impedance earphone or headset you would like to use with your radio, you may need to use another tap on the audio transformer to connect to the device. The black wire should always be used as one connection. The gray wire provides 20,000 ohms, the blue wire 5,000 ohms, the green wire 2,500 ohms, the yellow wire 1,200 ohms, the orange wire 600 ohms and the red wire 300 ohms. I happen to have a very old pair of high impedance headphones from about 1920 that are designed for crystal radios. It works well when connected to the yellow wire of 1,200 ohms impedance. Modern headsets and earbuds are mostly low impedance devices that will not work with the crystal radio. However, if you pass the signal through the amplifier you will build (which has a high impedance input and low impedance output), then you can use your modern headphones to listen to your crystal radio. The amplifier works well using the 10,000 ohm violet wire connection to the transformer, the same as the earphone supplied with the radio kit.

Impedance is a measure of the resistance to alternating current that a device presents to a connected signal. It is not the exact same thing as a pure resistance, which we can call ohmic resistance. Impedance also accounts for something called *reactance*. Inductors (coils) have reactance, a kind of resistance to current flow as already mentioned. Impedance is a measure of resistance that accounts for the combined effects of ohmic resistance (like a resistor) and reactance (like a coil). In fact, the speakers that are used in radios that you typically use employ a voice coil attached to a diaphragm to convert an electrical signal to sound. The long length of wire used in the coil presents some ohmic resistance to current flow. Since the wire is wound into a coil, it also presents some reactance to current flow. Both of these are combined into a measure of resistance known as impedance. Typical speakers have impedances of 4 or 8 ohms and require much too much power to work with a crystal radio.

Keeping a Log for Your Radio Listening

Most people listen to radio for the programming content. However, if you are serious about radio technology, you may wish to maintain a log of your listening. It can be fun to see how many stations you can hear with your radio. The conditions for propagation of radio waves varies over time and it is probable that you will hear some stations at certain times and not at other times. Therefore, you should listen at different times of the day and night. By keeping a log, recording the stations you can hear, and the date and time, you will create a log of your listening. From this log you may discover some interesting trends. For example, some stations can be heard at night but not during the day.

Even though your radio is calibrated, you cannot know for sure the exact frequency for a station until you hear an announcement of the frequency by the radio announcer. Some stations announce this many times each hour and some do not announce their broadcast frequency very often. So it may be an exercise in patience on your part. The strong station in Cleveland, WTAM, broadcasts on 1100 kHz and announces their broadcast frequency several times per hour. The announcement may sound something like this: "This is WTAM eleven hundred." You may need to listen carefully to catch the announcement because it is usually done fairly fast. Don't expect to hear something like this: "This is station WTAM broadcasting on a frequency of eleven hundred kilohertz." You might have heard something like that 50 years ago but not today!

There are some amateur radio operators (Ham Radio) that have become big fans of the crystal radio. They have studied the construction of crystal radios and compete with each other to design radios capable of tuning stations from distant locations. In fact, one Ham Radio operator located in Hawaii was able to tune a station in Cuba with his special crystal radio. In the case of the radio you have constructed, we cannot expect that level of performance. In fact, if you hope to hear distant stations with your crystal radio, you will probably need to use an amplifier. After you finish your crystal radio you will build an amplifier to use with your radio. Then you will be able to tune many more local AM stations and also distant stations at night if you have a good antenna.

There are different modes of radio wave propagation that determine which radio stations you can hear and at what time of day or night. This also varies with the frequency of the radio signal. For long distance reception, frequencies above those of the AM broadcast band are more useful. These frequencies, between 2 to 30 MHz, are sometimes referred to as shortwave radio or high frequency (HF) radio. Some of the Ham Radio bands are included in this range. International radio stations also broadcast in this frequency range.

Radio wave propagation can be divided into two broad types called ground waves and sky waves. Ground waves travel close to the surface of the Earth and sky waves bounce off the Earth's upper atmosphere (ionosphere), which allows propagation to more distant locations. The bouncing of radio waves off the ionosphere depends on the amount of ionization. The ionization is caused by high energy radiation (UV light) from the Sun. Therefore, there is more ionization in the upper atmosphere during the day than at night. That is why radio propagation varies between day and night. This subject is considerably more complex than my short description might suggest, but we will leave it at this point for now.

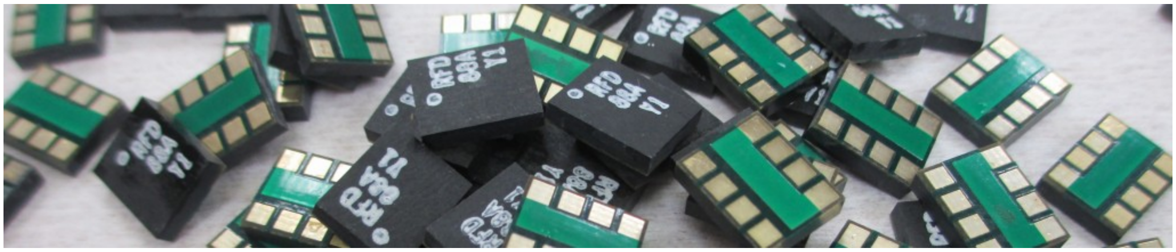
During the day radio wave propagation in the AM band is generally confined to the ground wave type. Ground waves don't travel much farther than the horizon. The distance to the horizon depends on the height of the radio transmitting antenna and its elevation above sea level. Nevertheless, propagation by ground wave is usually limited to 100 miles or less.

During the night the Sun does not shine on Earth's upper atmosphere and the degree of ionization of air molecules and atoms decreases. With these changes, radio waves of the frequencies used in the AM band can bounce off the ionosphere. When this happens it becomes possible to tune in AM stations hundreds of miles from your location. Therefore, if you want to try tuning in distant stations, you will need to try this at night. The signal strength of these stations will be weak and you will have much better luck hearing these stations if you connect an amplifier to your crystal radio. In addition, it is especially important to use a good outdoor antenna if you are trying to tune in distant stations.

As you build a log of listening, you may wish to gather more technical information about the distant stations you have been able to hear. A good web site to consult is the FCC (Federal Communications Commission) site for AM stations: https://www.fcc.gov/encyclopedia/am-query-broadcast-station-search . The information at this site includes the location of the station's transmitter (given in longitude and latitude) and the amount of power used by the station. Some AM stations are required to broadcast with lower power at night in order to avoid interfering with other radio stations operating on the same frequency (due to longer transmission distances at night). The FCC licenses a limited number of "clear channel" stations in various locations in the United States. These stations are required to transmit with 50,000 watts of power day and night and these clear channel stations are the most likely ones you will be able to hear from distant locations. There is a list of clear channels at this web site: https://en.wikipedia.org/wiki/Clear-channel_station . Our strong AM station in Cleveland, WTAM 1100, is a clear channel.

RF Diagnostics, LLC

WELCOME TO RF DIAGNOSTICS



Energy Harvesting Modules

WIRELESS ENERGY HARVESTING PRODUCTS RF Diagnostics, LLC designs and sells surface mount RF to DC converters and other building block modules for energy harvesting systems. With our products you can harvest ambient AC/AM/FM/Wireless Energy to power your IoT battery free system. We also provide custom designs for RF/microwave and general electrical engineering products and design contracting services to clients in the commercial wireless and defense electronics businesses. We strive to be a high quality and cost effective design resource for your design team.

OUR PRODUCTS

Microwave Energy Detector
This detector receives wireless energy at 2.5GHz and converts the signal to a DC voltage which powers a light emitting diode (LED). Place the detector on your microwave window or near your wireless LAN router and the LED will brighten and fade as the wireless field changes. No batteries needed!

OUR DESIGN SERVICES

Energy Harvesting Module & System Design

Any of our standard products can be customized for your application. We can support your application with matching, testing, antenna design, assembly and many other tasks. Have a new idea for a product? We can help you realize it. We are developing new products and are always interested in your feedback to guide our product development.

MMIC Design

We use Agilent's Advanced Design System for MMIC design and PCB design. Previous designs completed are quad-band GSM power amplifier modules, 2.4-2.5GHz/5-6GHz wireless LAN power amplifiers, broadband power amplifiers, switch-filter designs, RFID detectors, RF/DC converters and filter designs.

Front End Module Design

We use Agilent's Advanced Design System and Orcad PCB Editor for Front-End Module designs. Previous design examples are high-volume switch filter modules, dual-band 802.11a/b/g front end modules, 76GHz car radar module, RFID card design.

RFID Detector System

On an NSF Phase I & II grant to one of our clients, operating as a subcontractor, the RF Diagnostics design team created a complete RFID MEMS resonator detection system. Both hardware and software were developed under this contract. The work was published at an SPIE conference in July 2010.

Build a Homebrew Radio Telescope

Explore the basics of radio astronomy with this easy to construct telescope.

Mark Spencer, WA8SME

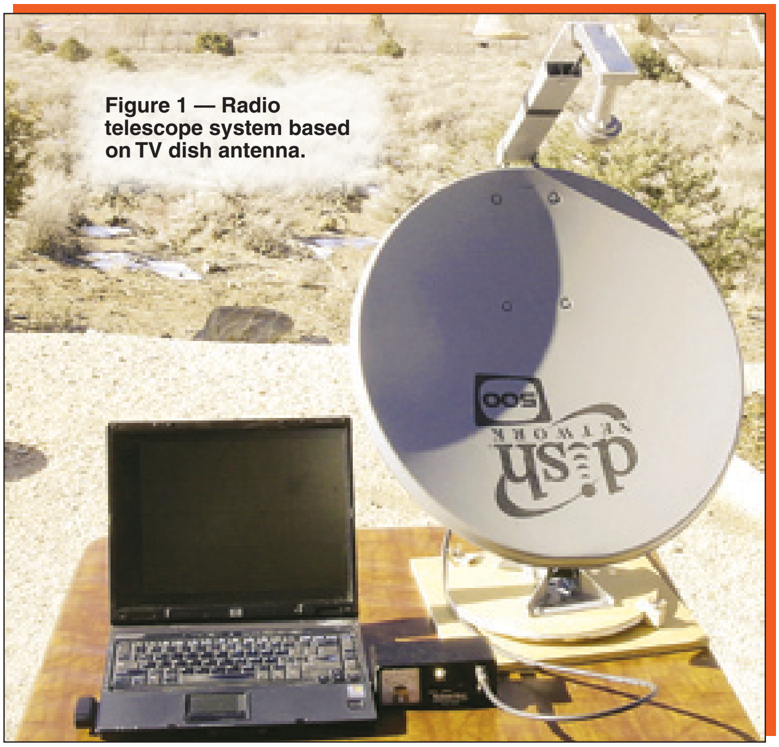

Figure 1 — Radio telescope system based on TV dish antenna.

There are many ham radio related activities that provide a rich opportunity to explore and learn more about the science of radio. One of those opportunities is radio astronomy.

All matter emits radio frequency (RF) energy dependent on the temperature and makeup of the matter, including the matter in space. The foundation of radio astronomy is to study the heavens by collecting and analyzing the RF energy that is emitted by bodies in space, very much as optical astronomers use light energy collected by telescopes. It sounds complicated. While professionals use very sophisticated and expensive equipment, you can, with some simple equipment and a little investment, build a radio telescope that will allow you to learn and explore the fundamentals of radio astronomy.

A Homemade Radio Telescope

In this article, I will build on an existing design of a radio telescope made from one of those ubiquitous TV dish antennas that you see around your neighborhood. The radio telescope (RT) project described here can easily be reproduced. Although this is not a fully capable RT, it can provide a wonderful learning opportunity for you, or perhaps students in your local school.

Figure 1 shows the radio telescope set up. The major components include a modified TV dish antenna mounted on a wooden support structure to allow pointing the antenna, a commercial satellite signal strength detector that displays the signal strength of signals collected by the dish on a meter and an interface that converts the signal strength into a amplitude modulated tone. The tone is fed into a computer sound card and finally a computer and software graphically displays the signal strength as a function of time.

The TV dish modifications are structural, and any available TV dish system can be used. The signal strength detector costs between $40 and $65 and is widely available from Web retailers. The interface circuit, which will be described shortly, is easily duplicated and costs approximately $20. Finally, the display software is free.

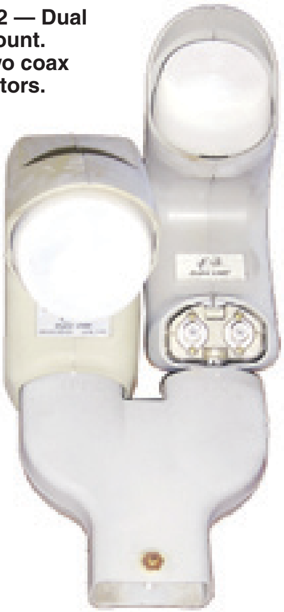

Figure 2 — Dual LNB mount. Note two coax connectors.

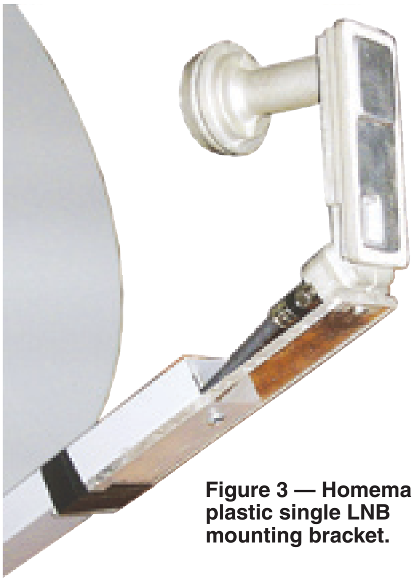

Figure 3 — Homemade plastic single LNB mounting bracket.

What it Can Do

The following is just a sample of what you can do with this simple RT:

- Use the sun to study and determine the beamwidth of the dish and verify the mathematic formula that is used to predict dish antenna performance.
- Measure the radiation intensity of the Sun and perhaps detect changes in solar activity.
- Measure the relative changes in the surface temperature of the moon.
- Learn about and explore a common radio astronomy collection technique called the *drift scan*.

Figure 5 — CM satellite signal strength meter.

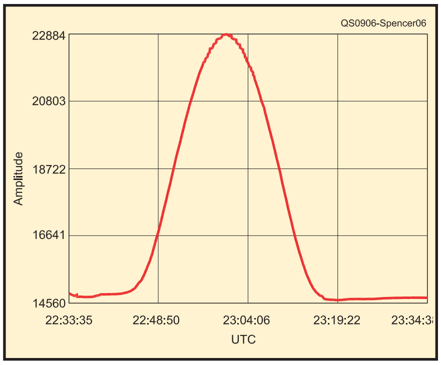

Figure 6 — *SkyPipe* screen showing antenna response.

- Explore the fundamental principle of energy emission as a function of temperature by detecting the relative differences between the temperatures of emitting bodies.
- Detect satellites parked along the Clarke Belt in geosynchronous orbit and illustrate how crowded space has become.
- Detect the Earth's rotation around the Sun and the Earth's spin on its axis by comparing daily drift scans of the horizon.

Antenna Subsystem

The basic RT system is based on the "Itty-Bitty" design that is described in two Web pages.[1,2] The TV dish is an offset 18 inch dish that has down converter(s) mounted at the focal point of the dish. The down converter is called a low noise block (LNB). The LNB is a preamplifier/down converter that converts the satellite signals from around 12 GHz down to around 2.4 GHz. Most modern dishes have two or more LNBs to access more than one TV satellite at a time without changing the pointing of the dish (Figure 2). The LNBs are mounted to share the focal point of the dish. Since only one LNB is required for the RT, I made a minor adjustment to the published Itty-Bitty design to position the single LNB at the dish focal point. Mounting the single LNB at the focal point really helps in pointing the antenna.

I used the existing LNB housing and mounting bracket as a template to determine the distance between the edge of the mounting arm to the mounting hole of the LNB. I then used a piece of plastic to fabricate a new mounting bracket for the LNB as shown

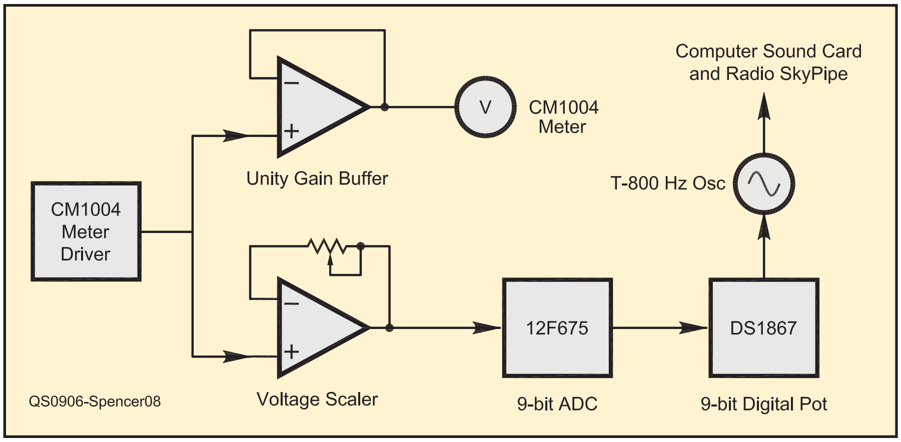

Figure 8 — RT Interface block diagram.

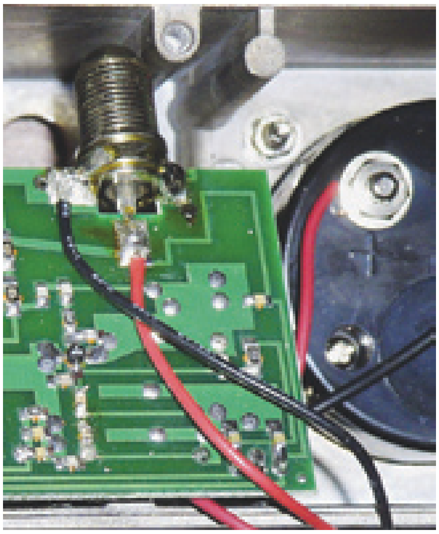

Figure 9 — Power and ground connection to CM board.

in Figure 3. The dimensions are not super critical, but careful placement certainly will improve the RT performance.

Some LNBs have two coax connectors. Only one will be used in the RT (Figure 4). It is a good idea to terminate the extra coax connector with a 75 Ω dummy load plug to balance the load on the LNB. The dummy loads for F type TV coax connectors are readily available from electronic parts retailers.

Note that the dish is mounted upside down. Though this orientation is not ideal for receiving satellite signals, this arrangement helps with pointing the dish in its radio telescope role.

Satellite Detector

The detector used in this project is the Channel Master (CM) satellite signal level meter model 1004IFD (Figure 5).[3] The CM is connected to the LNB. Power is supplied to the LNB through the coax connection from the CM. The CM detects the signal coming from the LNB and gives a meter indication of the signal strength and also varies the frequency of an audio tone to help technicians point the dish at the desired satellite. As you move the dish through the beam coming from the satellite, the meter indication will increase and then decrease coincident with the pitch of the audio tone.

The Itty-Bitty plans detail how to connect power to the CM and in turn connect power to the LNB (this power connection is handled by the interface in this project). Though somewhat effective, the CM meter and variable frequency tone indications provide limited utility in detecting changes in signal strengths required for radio astronomy.

Display

To really study the signals received by the RT, you will need to see them displayed graphically on a strip chart. There is an excellent software package called *Radio-SkyPipe* that is posted on radio astronomy Web sites.[4] The free version of this software is a good place to start. *SkyPipe* uses the computer sound card to measure the incoming signal strength and graphically displays the signal strength as a function of time. Figure 6 is illustrative of a signals detected by the RT. *SkyPipe* is very easy to use but some study of the HELP files will make it easier for you to fully tap into the capabilities of this software.

SkyPipe requires audio signals to be fed into the sound card MICROPHONE jack. The output of the CM detector is either an analog meter reading or a frequency modulated (constant amplitude) tone that is not really compatible with *SkyPipe*. An interface is required.

Interface

What is required to make the CM output work with *SkyPipe* and a sound card is to convert the signal level into an amplitude varying audio tone. The interface designed to do this is shown in Figure 7 and as a block diagram in Figure 8. Refer to the block diagram during the description of the interface function.

The unity-gain op-amp is used as a buffer between the CM meter driver circuit and the analog meter. The other op-amp is used as a voltage multiplier to scale the CM meter driver output voltage to match the 5 V reference voltage of the following analog to digital converter (ADC). The variable resistor in this voltage multiplier circuit is used to calibrate the CM to *SkyPipe*. The voltage from the multiplier is fed to a programmable interface controller (PIC) that is programmed as a 9-bit ADC to covert the analog voltage that is a function of received signal strength to a 9-bit digital word that is used to control a digitally controlled variable resistor. The interface includes a simple Twin-T audio oscillator circuit that provides a tone of approximately 800 Hz that is fed to the computer sound card. The amplitude of this audio oscillator is varied by the digital pot that is being controlled by the PIC. The result is the audio amplitude being varied in step with the signal strength detected by the CM.

The circuit provides power to the CM and the LNB. A 12 V source in the CM is tapped through an RF choke and this is connected to the LNB coax connector inside the CM (Figure 9). The 12 V is also regulated to 5 V to provide power to the interface. Though probably not required, there are two 5 V sources, one for the digital components of the interface, and the other for the analog components with one common ground point. This arrangement is used to isolate potential digital and analog noise sources within the circuit.

The interface is built on a circuit board and mounted right inside the CM box

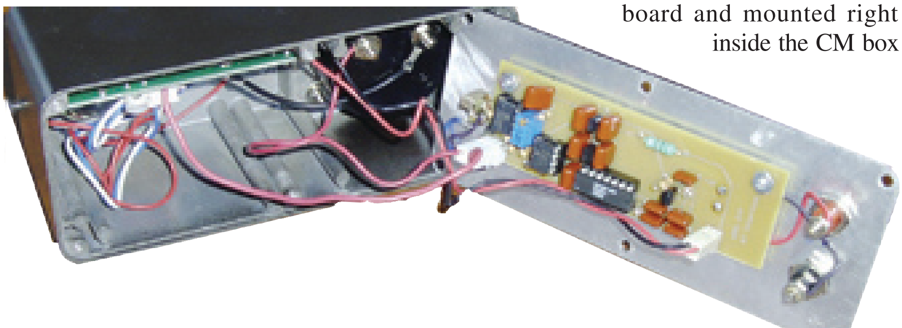

Figure 10 — CM with interface board.

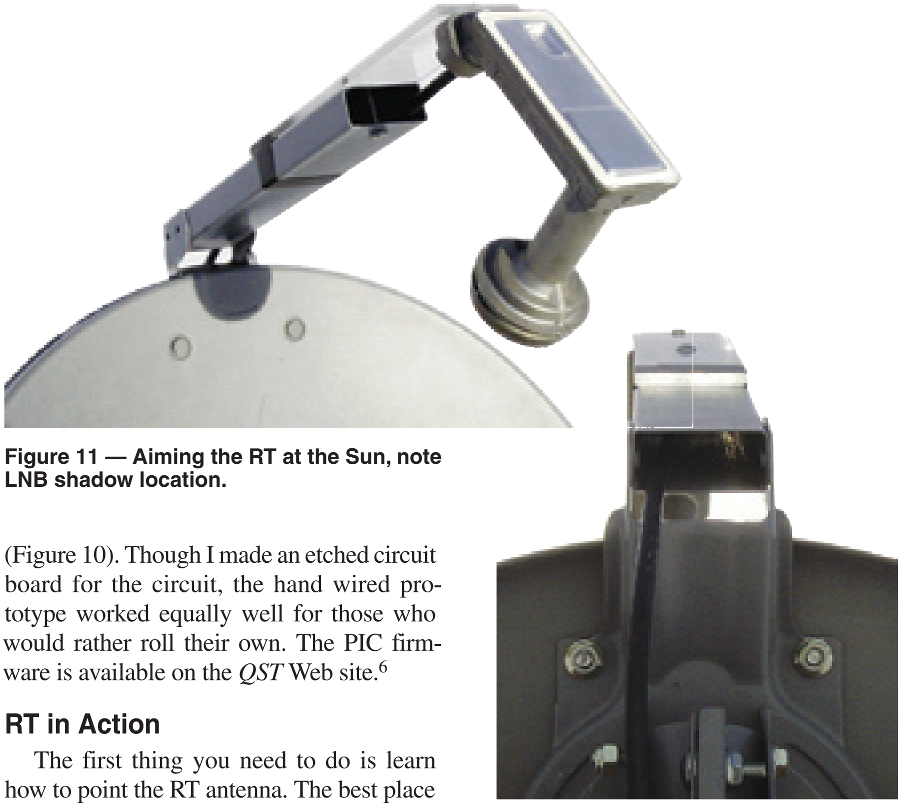

Figure 11 — Aiming the RT at the Sun, note LNB shadow location.

(Figure 10). Though I made an etched circuit board for the circuit, the hand wired prototype worked equally well for those who would rather roll their own. The PIC firmware is available on the *QST* Web site.[6]

RT in Action

The first thing you need to do is learn how to point the RT antenna. The best place to start is to connect the CM to the antenna and point the antenna at the Sun. *Caution*: Do not look into the Sun as you do this, or at any time. Adjust the pointing angle and elevation until you get peak signal strength as indicated on the CM meter or hear the highest pitch audio tone. With the antenna pointed directly at the Sun, take note of the position of the shadow of the LNB on the surface of the dish (left in Figure 11). If you look from behind the dish, along the LNB

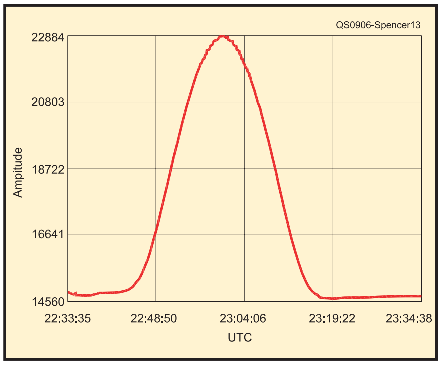

Figure 13 — Drift scan of the Sun indicating antenna's azimuth pattern.

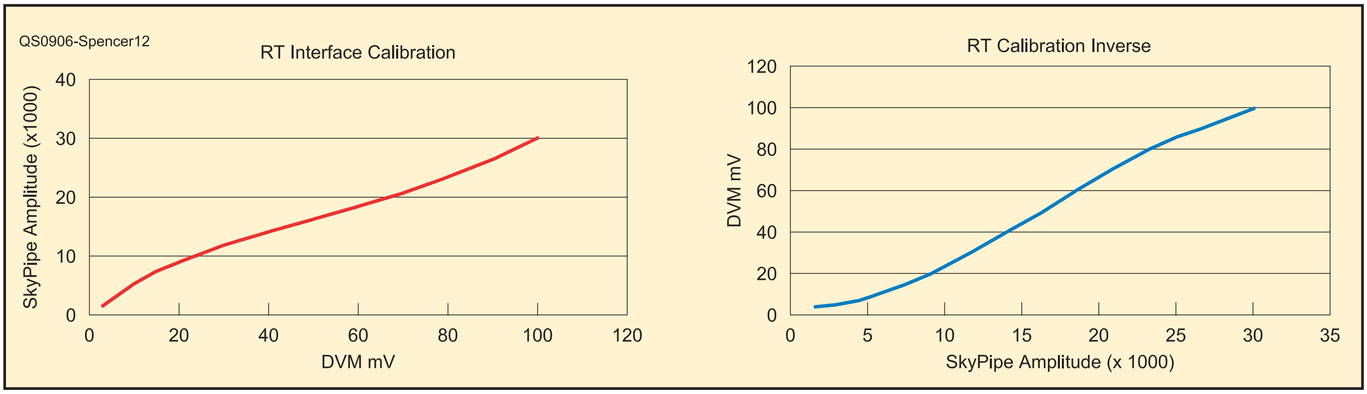

Figure 12 — Example calibration curves.

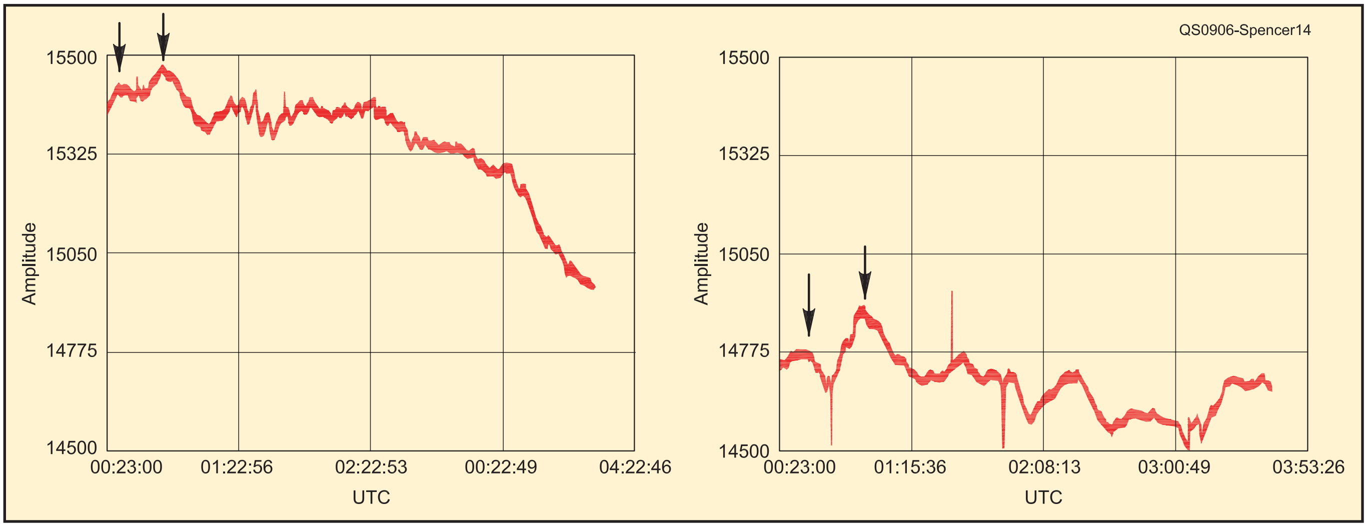

Figure 14 — Sequential drift scans. Note the time offsets between the peaks.

From June 2009 QST © ARRL

supporting arm (between the arm and the rim of the dish), you will see the Sun being blocked by the LNB.

Once you have the RT set up, it needs to be calibrated to match the output of the CM to *SkyPipe*. I have developed an *Excel* spreadsheet template to help with the calibration and a few of the other activities that you can accomplish with the RT (also available from the *QST* Web site). Turn the RT to a signal source, the Sun, or the side of a building would work. Turn the gain control of the CM to set the meter to maximum. Run *SkyPipe* and adjust the variable resistor on the interface board until you get a reading on the *SkyPipe* graph vertical (y) axis of approximately 32,000. With the maximum value set, adjust the CM gain control through the voltage range (0 to 100 mV) in 10 mV steps and record the corresponding y axis value on *SkyPipe*. This data is entered into the *Excel* spreadsheet to compute the calibration curve between voltage and y axis value. Both voltage and y axis values are used in analyzing recorded signal strength data (Figure 12).

A good first activity is to do a drift scan of the Sun. A drift scan means that you set the antenna azimuth (AZ) and elevation (EL) to some fixed pointing angle and allow the Earth to serve as the rotator to drag the antenna across the sky. To do a drift scan of the Sun, first set the elevation and azimuth to point directly at the Sun (maximum signal) and then move the azimuth toward the west (leave the elevation set) until you are off the peak signal. Now start *SkyPipe*. In about 15 minutes, the Sun will pass through the antenna pattern beam width and the result will be as illustrated in Figure 13. You can also use this collection technique to explore the antenna performance parameters.

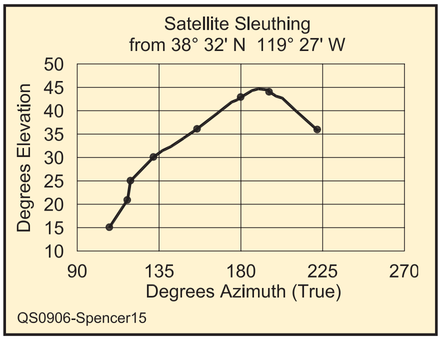

Figure 15 — Clarke Belt plot — tracking down satellites.

A good second activity is to do two drift scans of the night sky on two consecutive nights (beginning the scans at the same time each night) using the same fixed antenna azimuth (AZ) and elevation (EL). Figure 14 shows two such drift scans. Although at first glance they may not seem similar, there are some interesting features that are pointed to by arrows. If you compare the time that these two peaks occurred, the time difference is about 4.5 minutes. This shift is the result of the distance the Earth had traveled during the 24 hours between collections. This illustrates that the Earth's rotation as well as its travel in orbit needs to be considered when comparing drift scans. Enough to make your head spin (pun intended)?

A final good starting activity is to point the antenna toward the Clarke Belt and find all the satellites in geosynchronous orbit transmitting on 12 GHz. If you record signal strength peaks and AZ and EL for each peak, you will develop a graph of the Clarke belt as illustrated in Figure 15.

I have only scratched the surface, and the sky is the limit of this little project. The RT project can certainly broaden your horizons and expand your understanding of our universe. If you would like more detail than can be presented here, please contact the author.

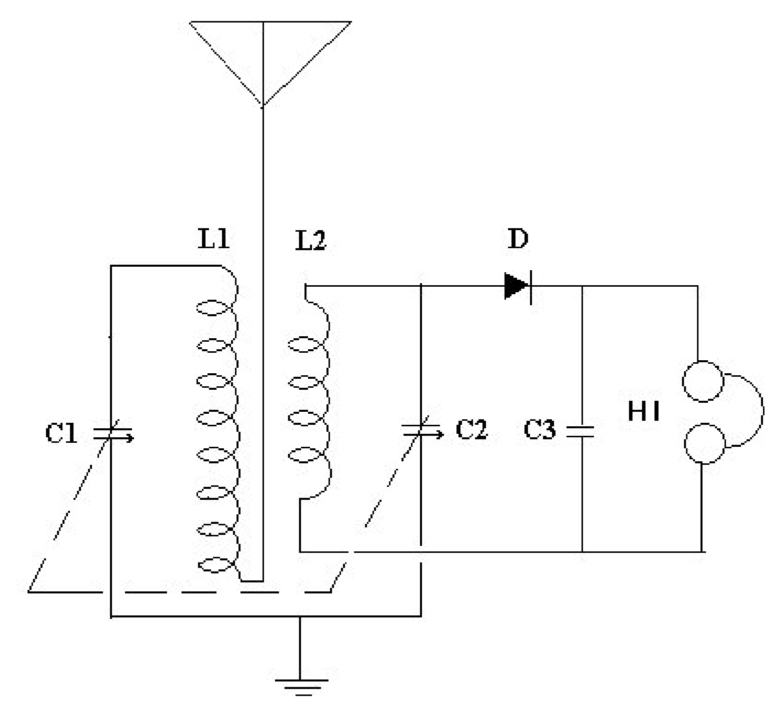
Double-ganged Mystery Crystal Set

copyright © 2006 by Larry J Solomon

Here's another great performer based on the Mystery set. This one uses a 500 pF döppelganger.



C1, C2 - 500 pF double-ganged air-variable capacitor
C3 - .001 uF capacitor
D - 1N34A diode or rock crystal
L1 - 50 turns #24 awg
L2 - 25 turns #24 awg wound in tandem with middle of L1

The Coil is air-spaced on each end of L1. L2 is close-wound with L1 after 12 turns of L1. Coils are wound in same direction. Coil form is 2.625 inches high by 2.375 inches in diameter. Although a high impedance headphone is shown, the set can be directly connected to the magnetic phono input of an amplifier instead of the headphones.

My DIY radio wave energy harvesting circuit

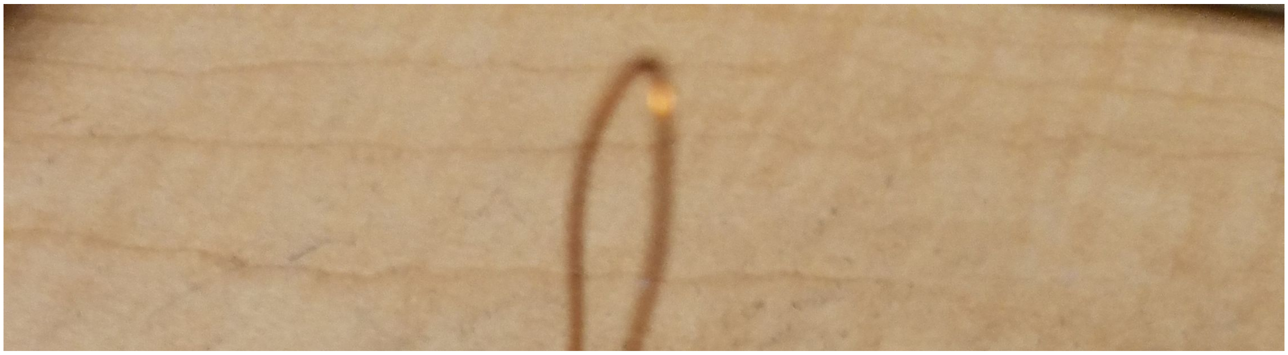
proteus-h (61) (/@proteus-h) in **technology (/trending/technology)** • 2 months ago

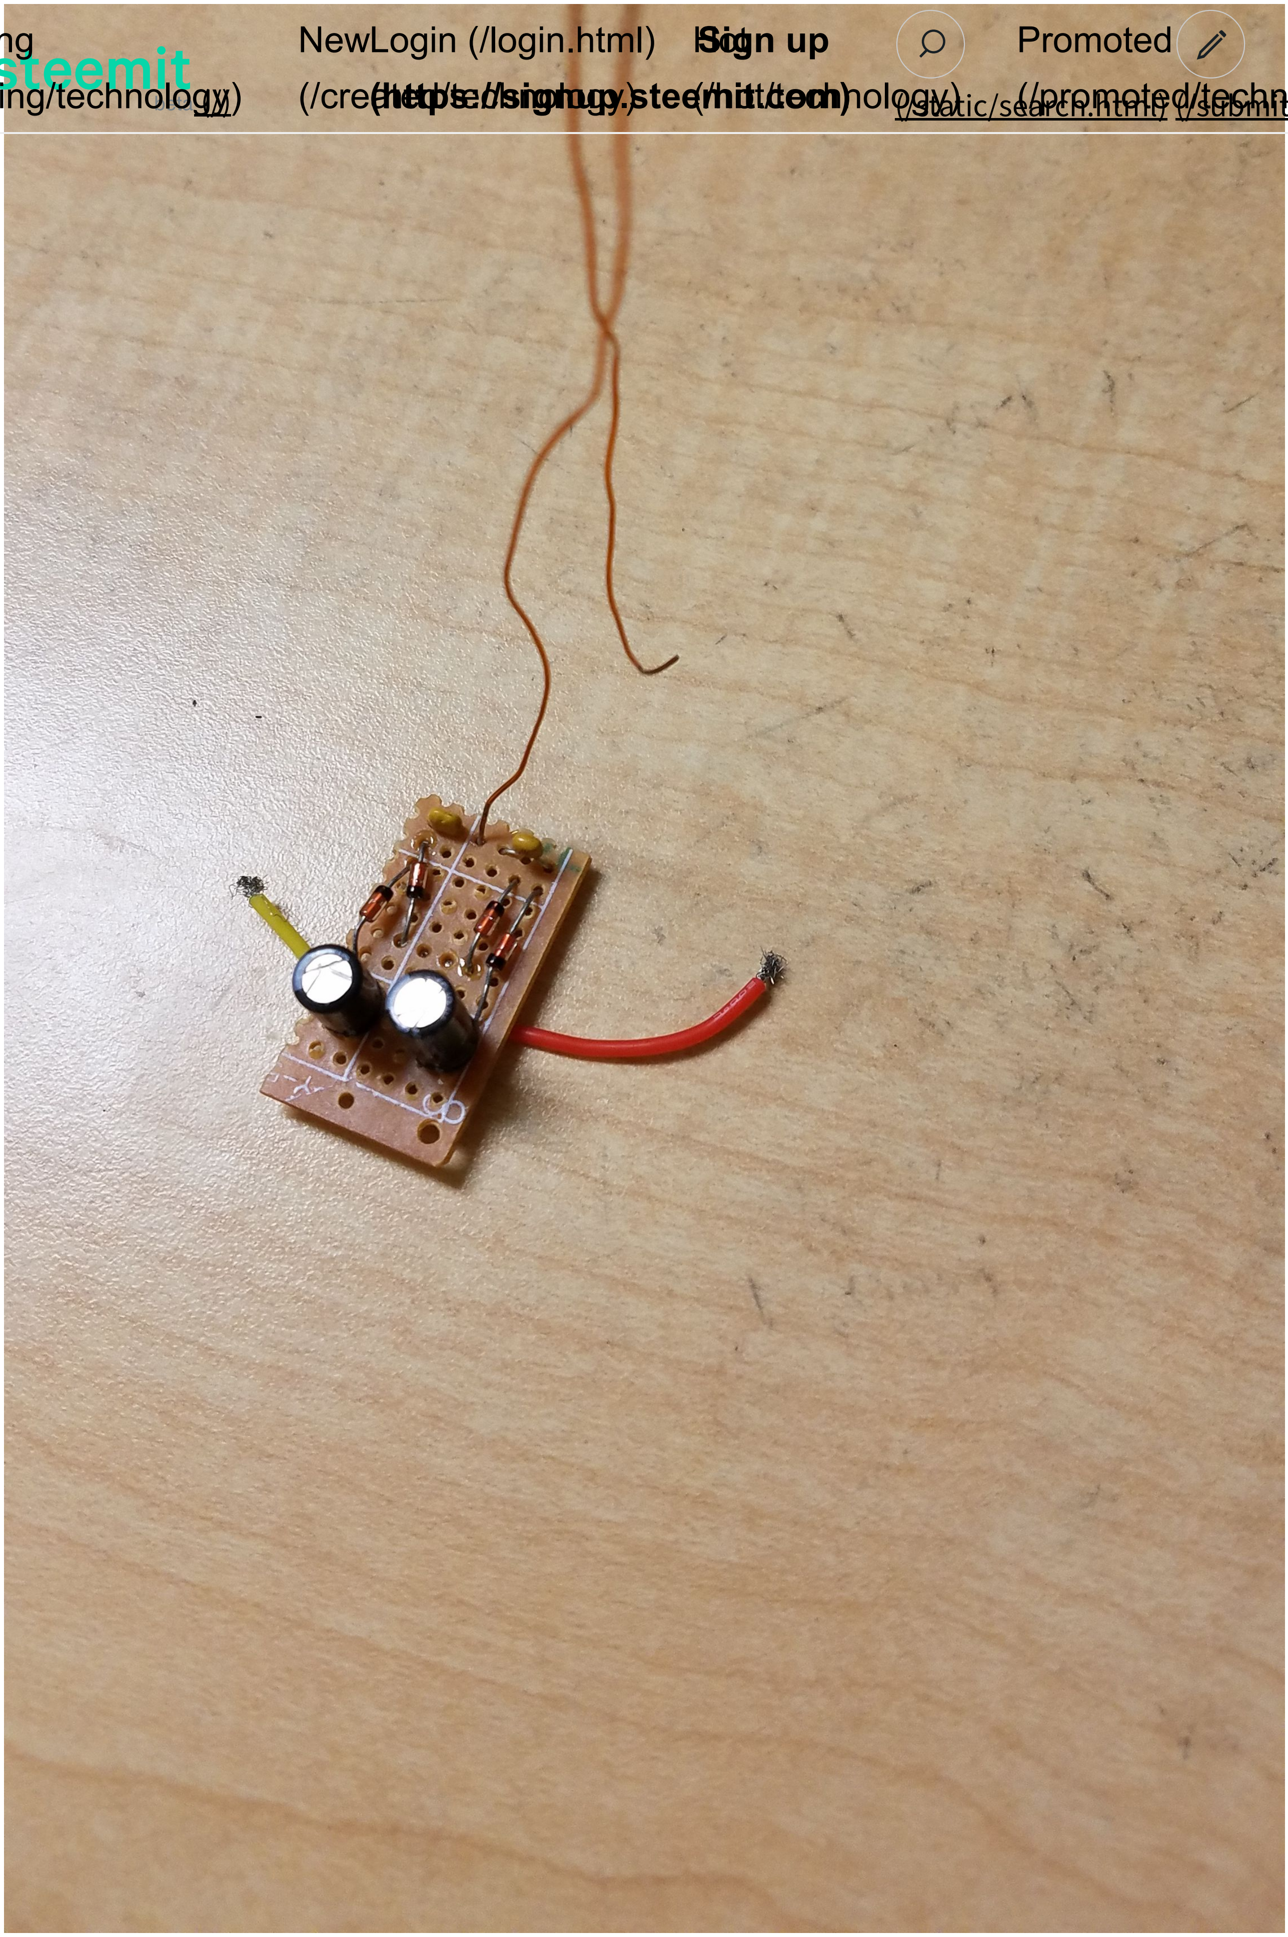
Here's a writeup of a simple radio-frequency energy harvester I built earlier this year. Now that I'm back at my apartment with my equipment I should be able to post more DIY projects. This device is crude, unoptimized, and imperfect ... *but it works*.

This super simple circuit converts radio waves collected into a crude wire antenna into electrical energy which is stored onboard two electrolytic capacitors. This is not a "free energy" device because it actually works: All of the energy brought into the capacitors comes directly from the energy of electromagnetic waves. You can build your very own harvester circuit with just 9 components and a piece of perfboard.

The actual amount of energy collected is absolutely tiny if you are only using ambient RF, so like most of my projects this is just a proof of concept. It's not going to charge a powerbank off of your cell phone emissions or anything like that ...

In case you don't want to get into the details, here's a picture of the completed crude harvester:





Operating Principles

Ambient electromagnetic radiation is all around you, harmlessly emitted from most electronics. Computers transmit 2.4 GHz microwaves for wifi/bluetooth and car FM transmitters transmit around 100 MHz to send audio to your car's radio receiver. Light itself is also, of course, electromagnetic radiation, but this device only works for much lower frequencies. I had the best luck around 100-200 MHz radiation. Electromagnetic radiation at these low frequencies (radio and microwave) is not ionizing and as such harmlessly passes through or is absorbed by your body.

EM radiation can be collected via antennas. Any radio receiver does this but only uses the captured radio wave energy to produce a detectable signal so that you can hear the broadcast. But these waves contain *energy*, and we can capture this energy and use it for other purposes, small as it may be.

Crystal radios (https://en.wikipedia.org/wiki/Crystal_radio), common starter DIY electronics projects, do just this. A crystal radio is a simple receiver that can be built from mostly scrap parts, and lets you listen to radio broadcasts *without a battery*. The crystal radio produces energy out of its piezoelectric speaker: Sound energy, that is. This energy *has to come from somewhere*, and in the crystal radio's case, it is harvested directly from the incoming electromagnetic radio waves.

A crystal radio receiver.
Image credit (https://en.wikipedia.org/wiki/Crystal_radio)

Other devices, such as passive RFID tags, also work by extracting energy from electromagnetic fields.

This device works on the same principle: Extract useful energy from electromagnetic waves. Here's the schematic for the circuit (found by me online - I didn't design this, although it is pretty simple)

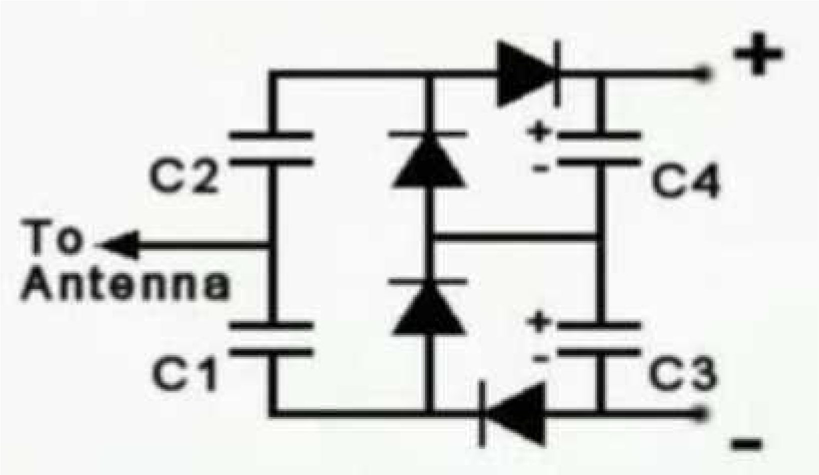


Image credit (https://electronics.stackexchange.com/questions/248525/circuit-for-free-energy-from-radio-waves)

Capacitors C1 and C2 serve to isolate the antenna. The antenna in my case is made from a piece of copper wire soldered to the two capacitors. The wire is probably 20 centimeters long and was not optimized with any particular frequency in mind (this was a quick project). The four diodes form a full wave rectifier that converts the incoming alternating current produced by the inbound radio wave into direct current. Capacitors C3 and C4 then serve to store the harvested energy in an electric field - think of them as tiny batteries. For C3 and C4, I used 100 microfarad capacitors rated to 35 Volts. These are very small capacitors but will store enough energy to easily measure on my cheap multimeter.

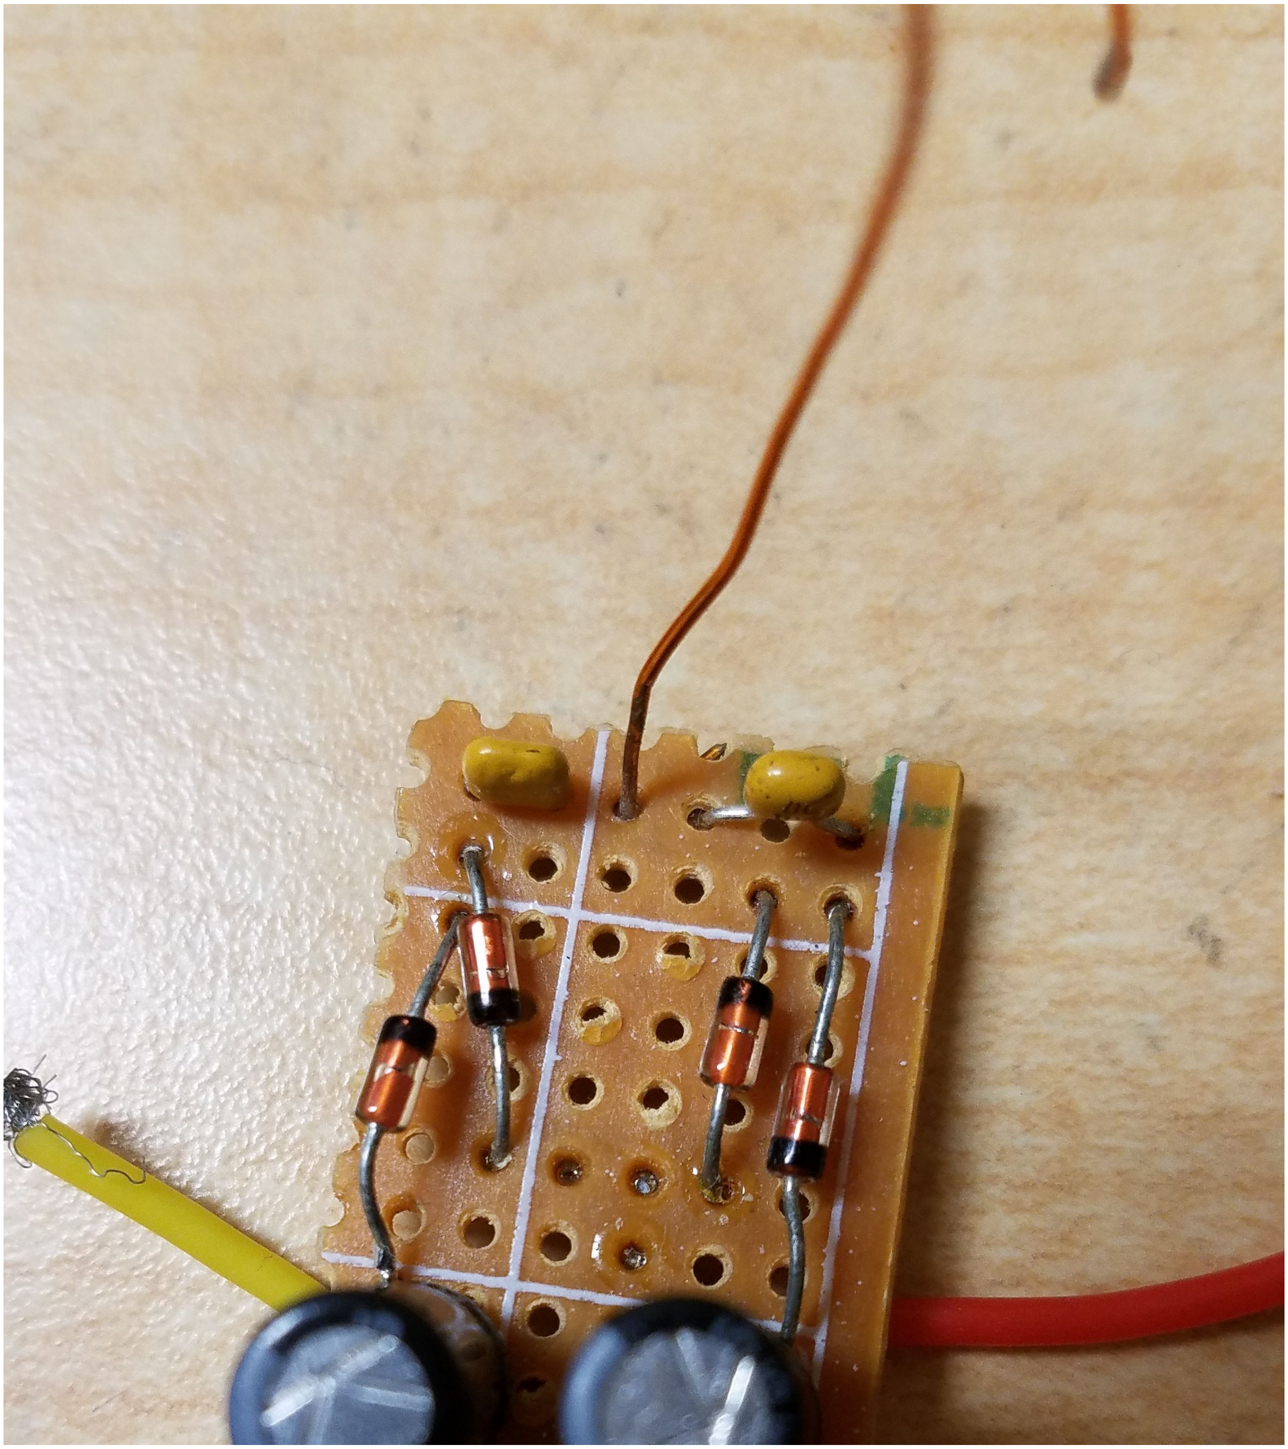
Assembly

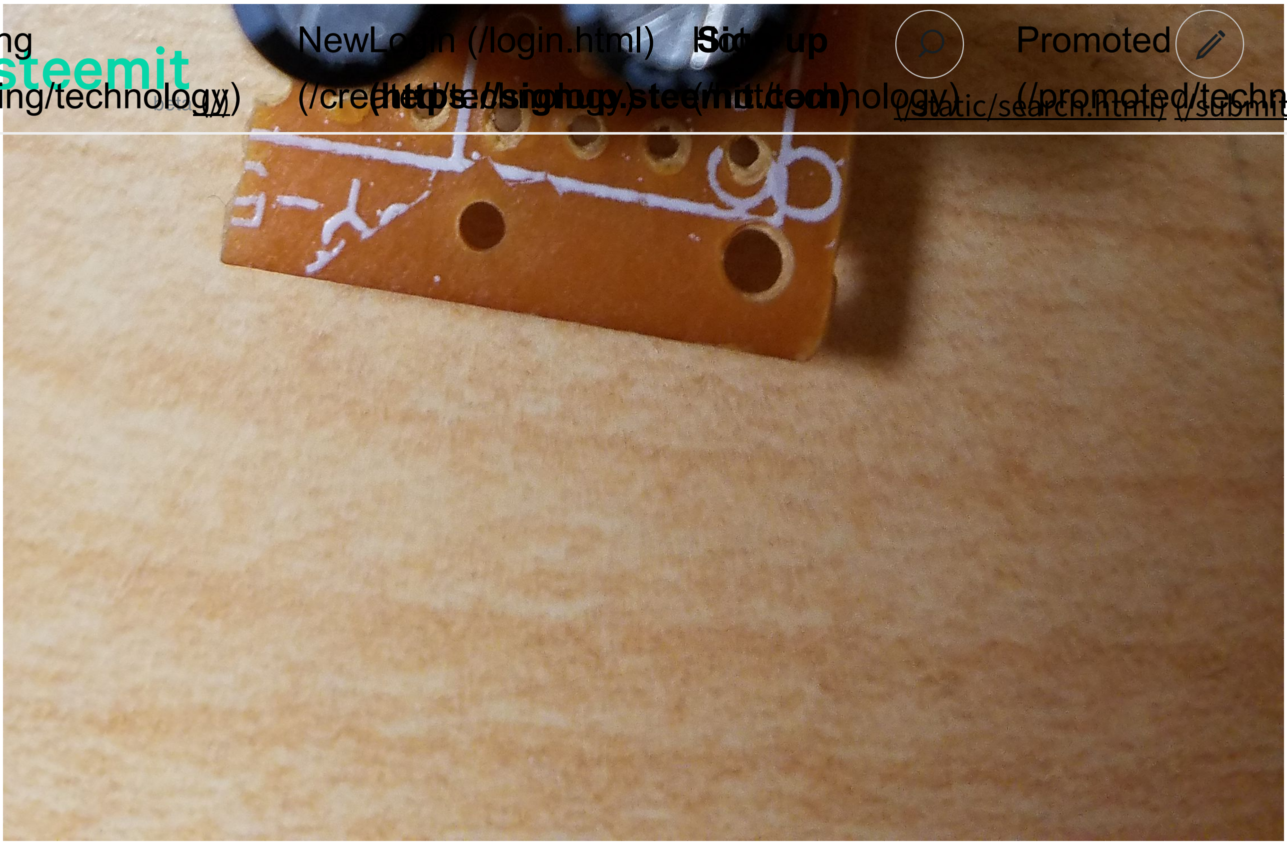
It's important to note that you can't just use any diodes for this and expect it to work. The diodes used need to be able to handle sufficiently high frequency and have a low voltage drop. To handle this task, I used the **1N34A Germanium diode** (I got some on Ebay for a reasonable price). You can peruse the datasheet here. (http://www.nteinc.com/specs/original/1N34A.pdf) In particular, these diodes are used for *FM radio detection* - this is essentially the same thing the energy harvester circuit is doing, since it is rectifying an input signal close to the typical FM band in frequency. Note that although the datasheet states that the forward voltage drop is 1 volt, this drop is much lower at the low currents we are dealing with here.

1N34A Germanium Diode
Image credit (https://www.radioshack.com/products/nte-1n34a-germanium-diode)

For assembly, I used a broken piece of perfboard I had lying around and a soldering iron to quickly connect all of the components. It is critical to get the polarity on the electrolytic capacitors correct. For the two capacitors connecting the antenna to the circuit, I used ceramic capacitors that don't need to be hooked up with a certain polarity. Once again, I used a badly optimized piece of wire as an "antenna" just to see if this would work. I unfortunately don't have the knowledge of RF theory yet to go much further, but the wire ended up working out just fine.

Here is a close-up shot of the final circuit. Yeah, I know it's ugly.





The red and yellow wires are just to make it easy for me to read the voltage on the storage capacitors - they are completely unnecessary.

I originally expected to get tiny (but detectable) energy generation, picked up on C3 and C4, just by leaving the circuit out in the room I built it in. When this didn't work, I thought it was broken. Turns out it wasn't: A ham radio transmitter confirmed that.

Using a Baofeng UV-5R handheld radio transmitter on the VHF band (~140 MHz) near the harvester causes the storage capacitor voltage to spike - so much so that I would be worried about them failing if the transmitter was left on for more than a few seconds. In a test I just did a couple minutes ago, quickly transmitting around 142 MHz (4W transmit power, nobody was using that frequency at the time) from a few inches away from the harvester caused the storage capacitors to quickly spike up to over 16 volts - not insignificant at all. This voltage was measured across the two electrolytic capacitors in series. In fact, this is easily enough to light an LED for a brief moment (or even break it, since LEDs are typically not rated for 16 volts).

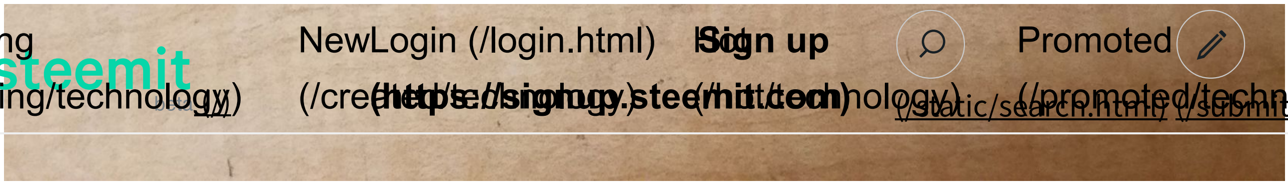
UV-5R



My UV-5R transceiver. I used this handheld to test the harvester circuit above. If you're looking to get into ham radio, I highly recommend this device because it's very cheap (~$25), is somewhat sturdy, and offers UHF and VHF transmission/reception.

The UV-5R transmitter proves conclusively that the harvester is actually working ... somewhat. While you can harvest pretty decent amounts of energy an inch away from a four watt radio transmitter, this isn't useful outside of an experiment since ambient RF is nowhere near that energetic. Detecting ambient RF with this thing would be nice ...

Well, I was able to do that too with this circuit. I just conducted another test where I shorted the storage capacitor and measured the storage capacitor voltage after 1 minute. The result: 18 millivolts. Here's the multimeter screen:

ETEKCITY
MEASURE UP

20
V⎓
200k
200
Ω
20k
50
000
50
V
200
200

Various other informal tests returned similar results. For some reason, the circuit does actually harvest tiny amounts of energy from radio waves in my apartment but not in the room where I originally built the circuit. Not sure why there is more RF here, but whatever. The capacitors hooked up to the harvester charge themselves without external power source ... other than the radio waves transferring energy to the circuit, of course, to conserve energy.

Of course, 18 millivolts (that's 0.018 volts ... you should be laughing here) is pretty damn useless. But once again, this isn't exactly intended to be a useful product. There really isn't a lot of energy in ambient RF waves floating around to begin with. This just showed that the circuit works on both low and high levels of incident radio waves.

Conclusion

I don't personally see a practical use for this device. Ambient energy collection produces too low a capacitor voltage to be useful (although I may try some lower capacitance capacitors to see if I can get a higher voltage more quickly, which could then be potentially useful like my nuclear battery was). While you could technically produce okay amounts of energy by strapping this to the back of your ham radio and collecting whenever you talk, you are technically hindering your transmission range in the direction of the harvester by doing this - again, the energy has to come from somewhere, and if you are taking energy of out of the radio waves leaving the transmitter, those absorbed waves don't get to make it to the receiver of whoever you are calling. For this reason, putting such a harvester on, say, your cell phone, would just make it more difficult to receive calls from cell towers in the direction of the harvester, since the harvester is essentially providing partial shielding by absorbing some of the RF emissions.

If there was a way to produce practical voltages from ambient RF using this, then I could see this being useful (even if just as a gimmick). This is of course totally possible, and electronics manufacturers have already built circuits that can do this. It's just a lot harder with DIY tools, big components, and only minimal understanding of RF antenna theory. But I'll probably keep trying and keep you posted if I have any luck.

I hope you learned something from this project! If you have any questions, comments, corrections, or rants, feel free to let me know. I hope to eventually improve this device a bit, so let me know if you have any suggestions for improvement!

I recently read about a company that is transferring power via waves between 1-5m. There must be some wave range where this works quite well then. Dont remeber where it was.

Wireless power definitely works, but it's usually pretty inefficient. After writing this I had the idea of using this harvester as an RF detector by adding an LED that lights up when it gets close to something transmitting by using energy in the storage capacitors. This would let you detect stuff like FM transmitters without seeing them. I'm going to try to throw it together and make a post in a few days about it if you're interested.

Enhanced Mystery Crystal Set Also Pulls in FM

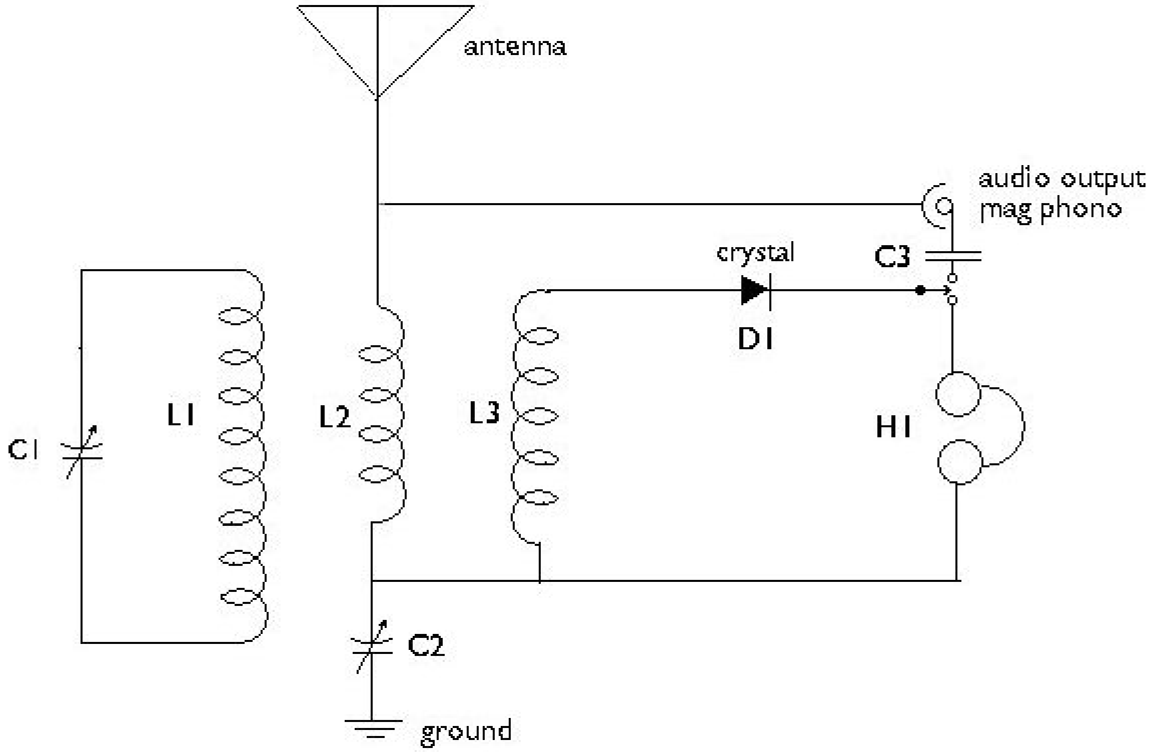
copyright © 2006 by Larry J Solomon

The Australian "Mystery Crystal Radio" has been praised since its original publication in 1932, but I don't think anyone has ever mentioned its capability for FM reception. To clarify somewhat, it is the Mystery Plus set, rather than the original circuit to which I am here referring. The original Mystery set had two coils wound in tandem, whereas the Plus set has three coils -- an extra one for antenna tuning. The only other substantive change I have made is an additional variable capacitor on the ground circuit, an outboard rock detector jack, and an audio output jack for playing through a sound system (optional). The capacitors cannot be ganged. Here is the circuit.

Enhanced Mystery Crystal Radio

with Optional Audio Output and FM Detection

© 2006 Larry Solomon



Parts List

C1 350 pf air variable capacitor

C2 350 pf air variable capacitor

C3 2750 pf capacitor

L1 45 turns 22 gauge magnet wire

L2 15 turns 22 gauge magnet wire wound on top of L1+L3 and separated from them by a layer of duct tape

L3 25 turns 30 gauge magnet wire wound parallel to L1 after the twelfth turn of L1

H1 high-impedance headphones

D1 Detector: 1N34 germanium diode or crystal rock detector

Coil form 2.75" diameter and 3" long (PVC pipe)

*original Mystery circuit: The Sunday Mail - Brisbane, Australia, April 16, 1933

This set is an amazing performer. It has crystal clear reception, good sensitivity, and excellent selectivity. To my surprise, in addition to the expected panoply of AM stations, I heard a faint signal that I could not

tune out. At first I could not identify it. To my surprise I heard the announcement "KiiM FM, 99.5"! This is a country music station here in Tucson. It was all over the dial, untunable, but the much louder AM signals masked it when they were tuned in.

I set myself the task of trying to improve the FM signal. I tried some simple circuit modifications, which did not improve anything. Then I connected a dipole antenna instead of the AM antenna I normally use. Suddenly, the FM signal was much clearer, although still weak. By using the audio output and sound system amplifier, I was even more amazed that four different FM stations came in loud and clear. I found that changing the telescoping antenna length and position I could tune the stations in and out. They were KRQ, KLPX, KiiM, and KHYT all local FM stations with transmitters nearby. Their reception was also affected by the length and position of the audio output cable.

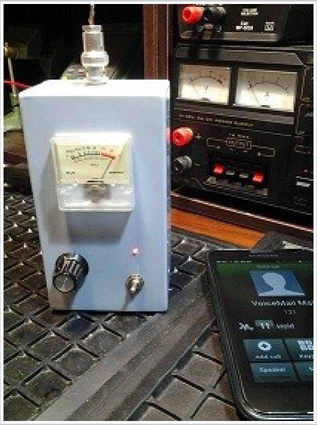
Building Your Own RF Field Strength Meter

By *Jestine Yong* on *June 1, 2013*

29 SHARES SHARE TWEET SHARE SHARE 34 COMMENTS

A simple and easy project for a rainy Sunday!



Why would you need one? Sometimes we build electronic projects for fun only, or just for satisfying our technical curiosity; this is what I do sometimes. This project, however, started with a need.

The need originated when a friend called for help to solve an intermittent problem with the UHF transceiver on his boat. The receiving ends reported frequent cuts in his transmission.

I quickly improvised a very simple Field Strength Meter composed of a small antenna, a detector diode, a resistor, capacitor and a Micro Ammeter. Assuming that this simple circuit would be sensitive enough to detect the HF field, providing we keep it close enough to the transmitting antenna. This worked quite well, and the intermittent problem was easily diagnosed and fixed; it was caused by a broken antenna cable, making intermittent contacts. With the meter we were able to see a clear drop of the field strength when moving the cable.

From there, the technical curiosity took over; what if we could improve the circuit, making it more sensitive and, how high in frequency it would still work? Would it work for much higher frequencies such as 2.4 GHz, to check RF fields from Wi-Fi routers and mobile phones?

I gave up (at least temporarily!) to the idea of building a wide range RF amplifier to amplify the antenna signal over that wide range of frequencies. This might be another project for another rainy Sunday (or many more rainy Sundays!). Instead, I preferred trying to amplifying the DC signal after the RF detection and see how far we can go.

And here we go; we have a very simple instrument that can detect the activity of your Wi-Fi router, your mobile phone and about any RF transmitter through a wide range of frequencies.

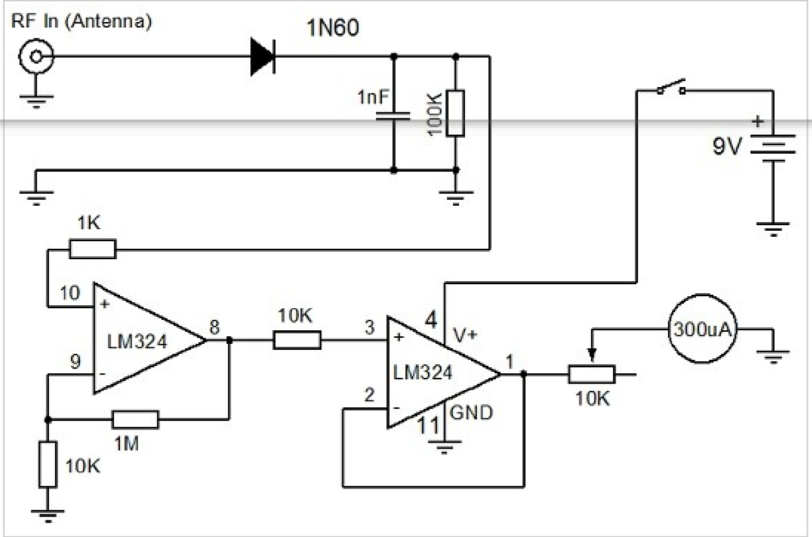

Fig. 1 Schematic diagram

It is powered by a 9 V battery. The diode is a critical component; it should have a low threshold voltage. The diode used in this circuit is a germanium diode 1N60. A ghost from the past, but it is still available on the market (Escol for example).

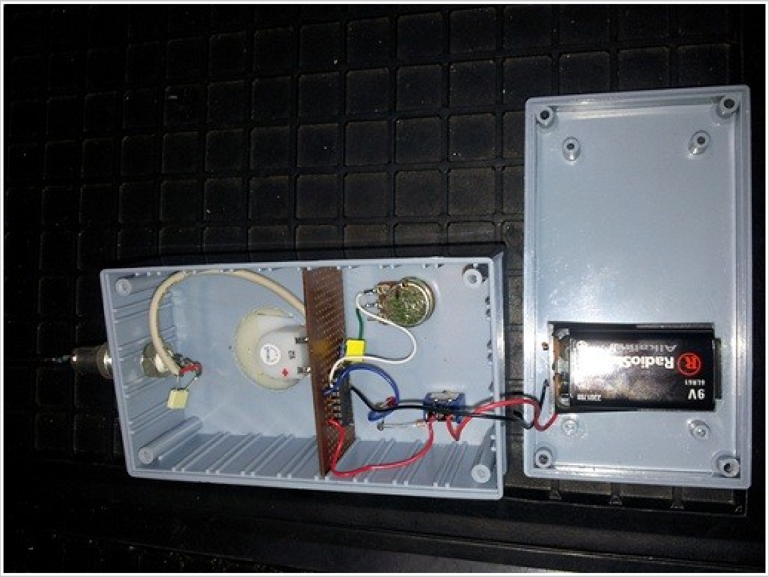

Fig 2. Inside the box. Plenty of space for further developments!

The diode and the 1 nF capacitor are soldered directly at the base of the antenna connector. In the next version of this circuit I would put the 100 K resistor there as well.

Another critical point is the antenna. It should be cut to ¼ wavelengths for the frequency range you

Advanced Electronics Repair

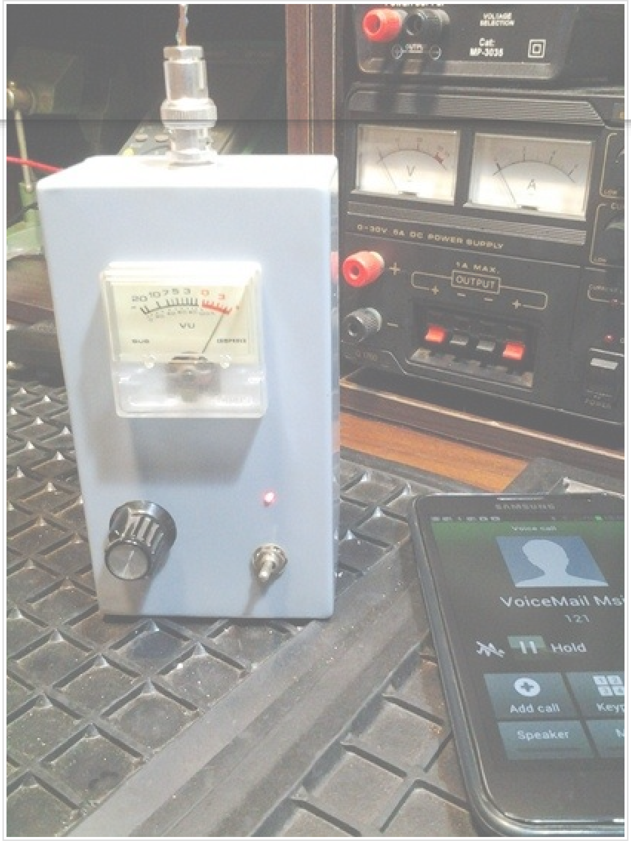

Fig 4. Reacting to the mobile phone transmission.

Note that the sensitivity button is at a quite low position, showing that the device it quite sensitive at those frequencies.

This project can be built with components we have in our drawers. Who want to go out buying components on a rainy Sunday? I used a Vu-Meter from a scrapped amplifier for the indicator. The scale is not important as the measurements are comparative anyway. Those Vu-Meters are quite sensitive. The OP Amp can be any one of the common type as we amplify DC only. I used one fond in a drawer…

Possible improvements:

– A power jack so we can power the device with an external power supply when it is convenient, saving the precious battery life.

– A better antenna with a better gain. This device can be used to compare the performances of various antennas.

– A wide range RF amplifier… maybe later.

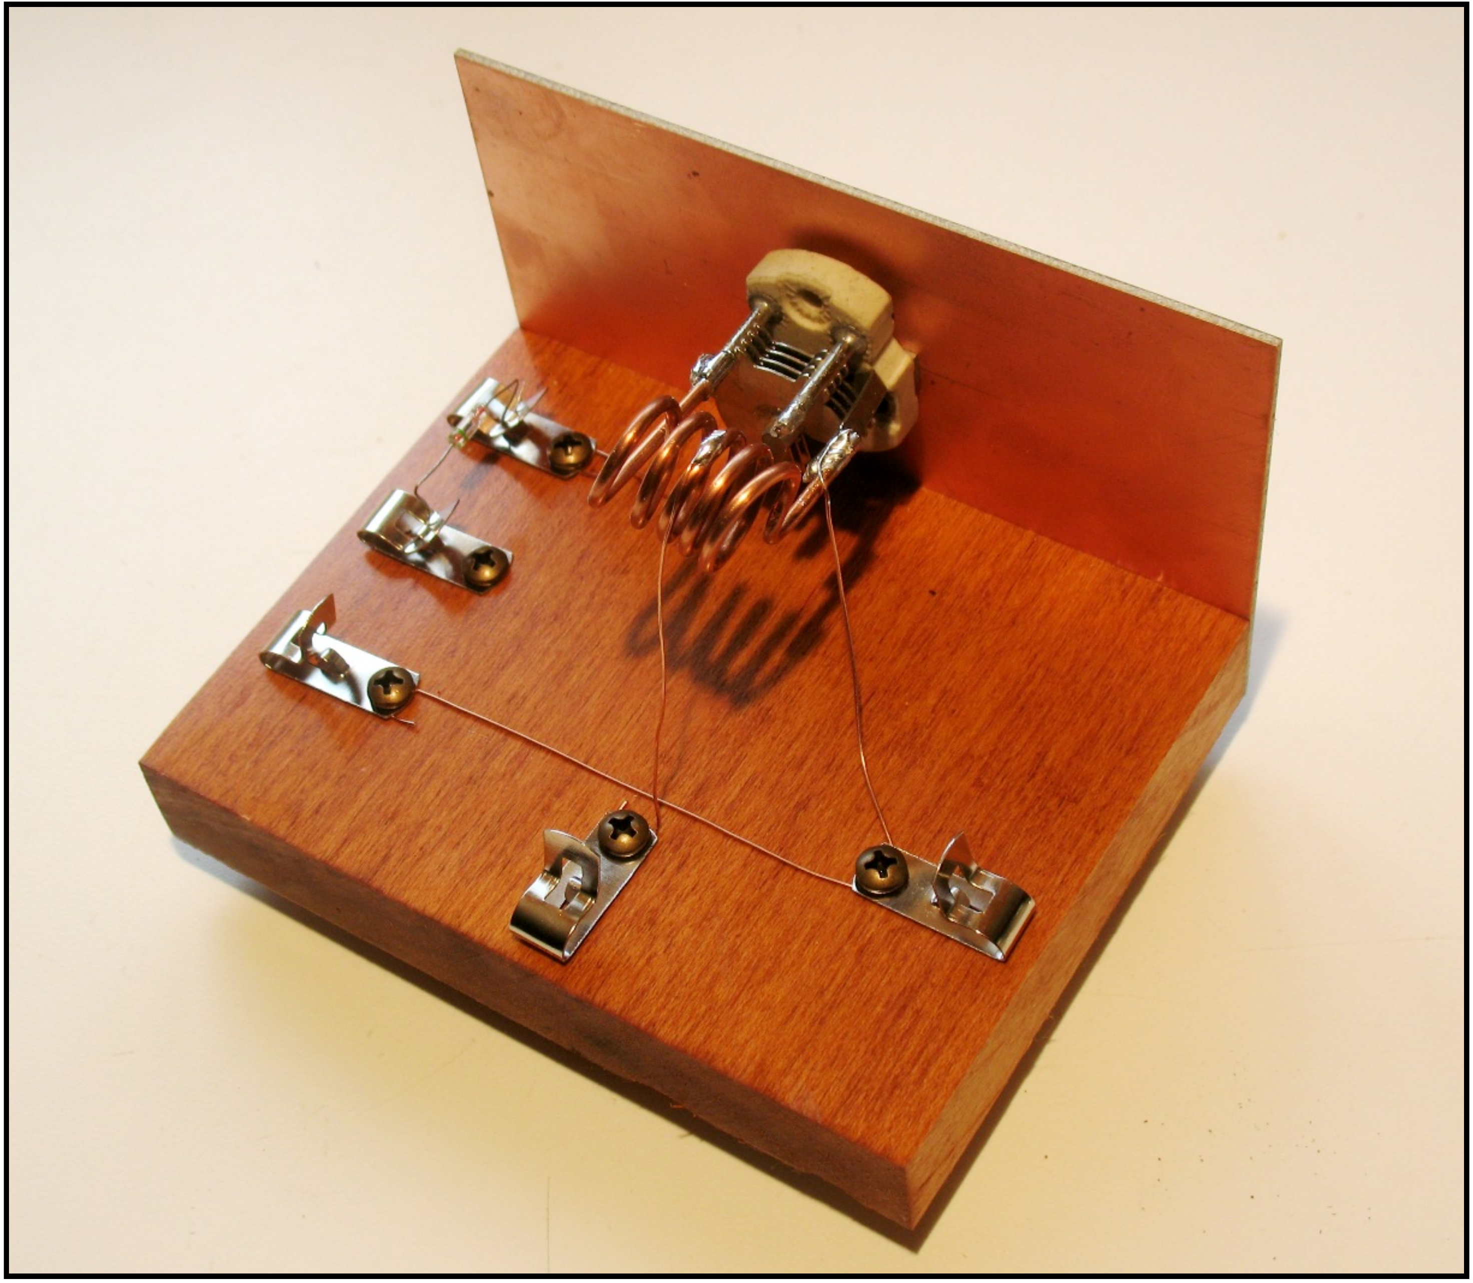
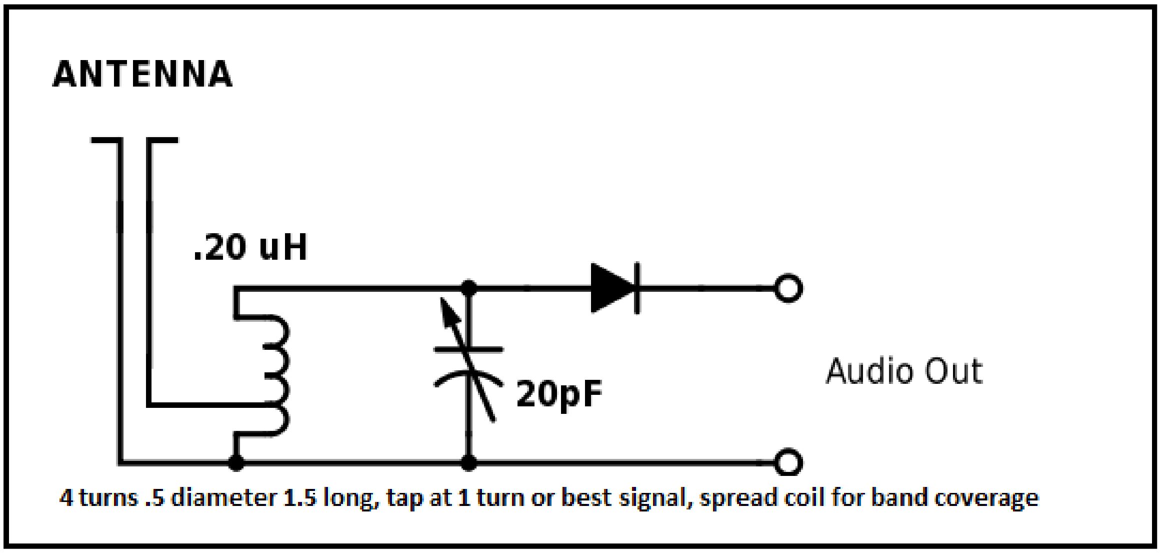
FM Crystal Set





ANTENNA
.20 uH
20pF
Audio Out
4 turns .5 diameter 1.5 long, tap at 1 turn or best signal, spread coil for band coverage

By slope detection you can get FM. If you live close to the stations you should do well with Hi Z phones. I use an audio amp, I am far from the stations. I get three.

Fighting the pollution by public radio broadcast antennas

Un texte en français :	La pollution radio par les émetteurs FM
Een tekst in het Nederlands:	De radiovervuiling door FM-stralen
A petition:	www.petition-electrosmog.be

The electromagnetic pollution has now reached such a level that not only hypersensitive persons are being harmed. The debate most often focuses on cell phones, their relay antennas, Wi-Fi routers and similar technologies. It is often pointed out that domestic appliances like power saving lamps and cheap electronic devices, are harmful too. Recently, I came to the conclusion that I too had problems with electromagnetic radiations. Yet after a few months investigating, I was surprised to find out that far out the main cause of my problems was nothing I had heard about. A 100 MHz FM public radio broadcast antenna is located atop a local hospital and burns the whole city with an astounding force of 2 V/m (pike value).

I found other persons that are harmed. For example people who develop severe headaches or tiredness after a few hours working in a given place. They have no problems in other places, that are less exposed to the FM radio waves. It seems to me that people who live in strongly exposed habitations often develop psychiatric problems. My guess is that probably several thousand persons in the city are severely affected. Maybe tens of thousands are affected but without getting obviously sick.

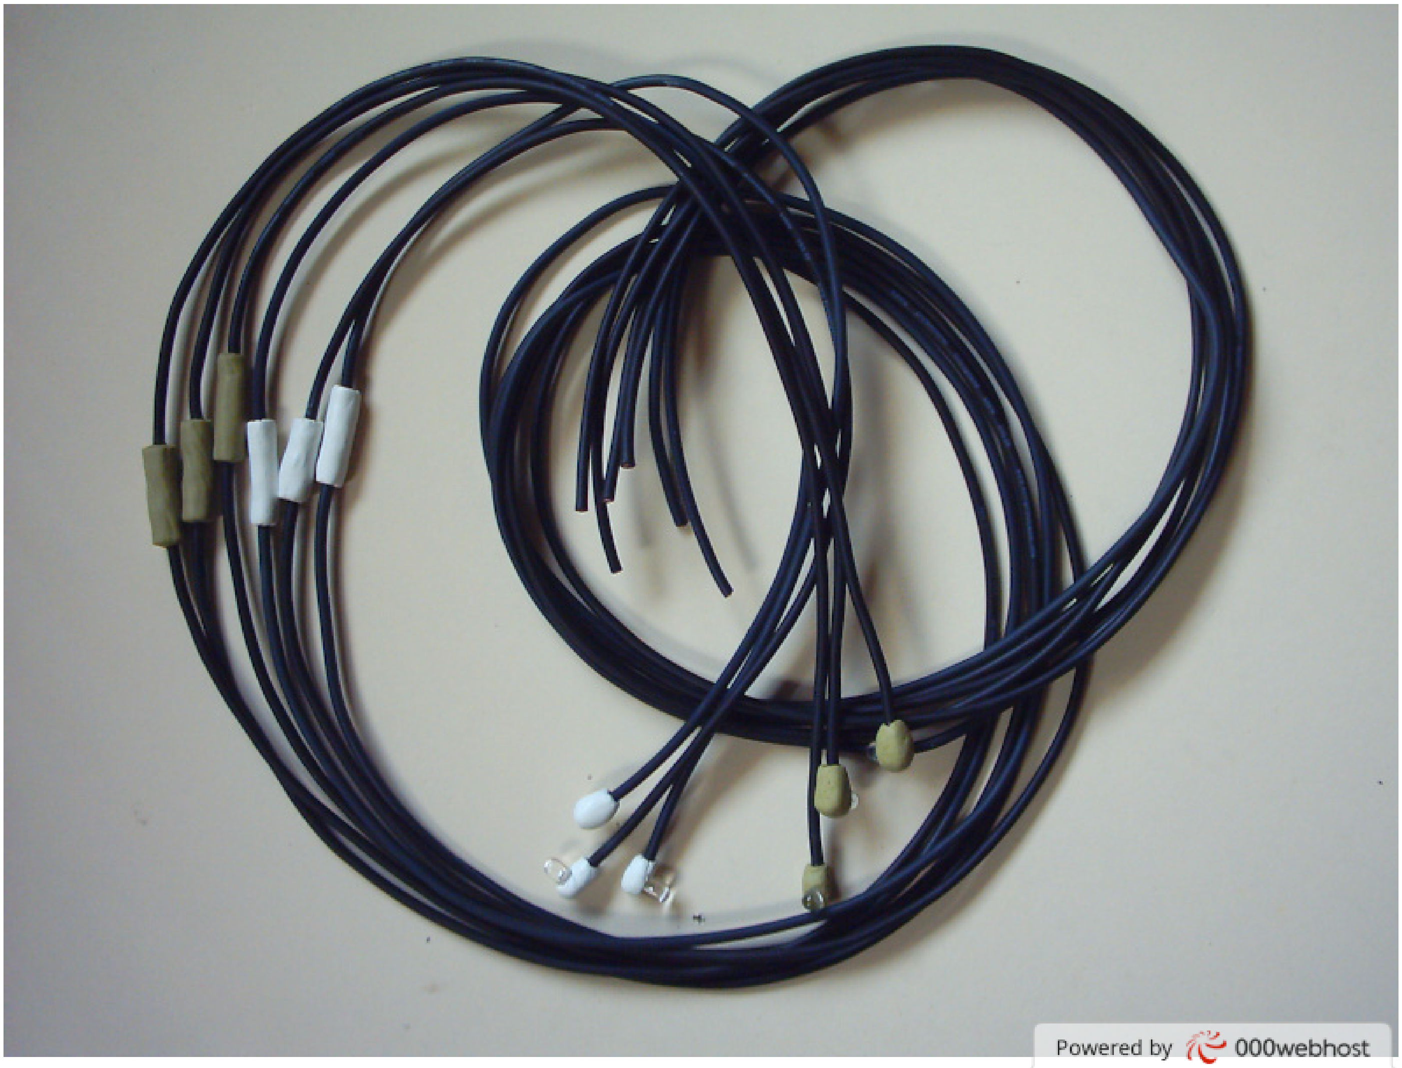
Most puzzling is the fact that this hammering by radio waves is completely useless. It wouldn't change anything to the quality of the reception by the listeners in the city, if the force of the radio waves was divided by 100 or preferably 1,000. The purpose of those antennas is to emit far away in the countryside. That's why they are located atop hills or tall buildings and they have a huge power. But, due to their rudimentary construction, quite much of that power is wasted and hits the nearby city.

It is legal to hit the ground with such force. Whether I measure in rooms or in the open, it is at worst a little below the norms. Hence the problem is with the norms. They keep being too high, despite the efforts of many scholars and health organizations. The situation is catastrophic. If the people did understand the harm that is done to their children, revolts would break open.

Below is a picture of a cheap calculator that I transformed. It contains no more battery nor solar power cell. Instead it draws its energy from a 1 meter long antenna. Anyplace in the city center, in direct view of the emitter, the power of the radio waves is strong enough to feed the device. I made this because nobody was frightened by the figures I was reporting, except some friends that are into electronics. Everybody knows that a car can kill even at 30 km/h speed but almost nobody has any knowledge about radio waves figures. When I showed the calculator, everybody understood and some whitened. (The calculator also works in some classrooms where I tried it out. The emitter was visible through the windows... Should I warn the parents of the students that failed their exams?)

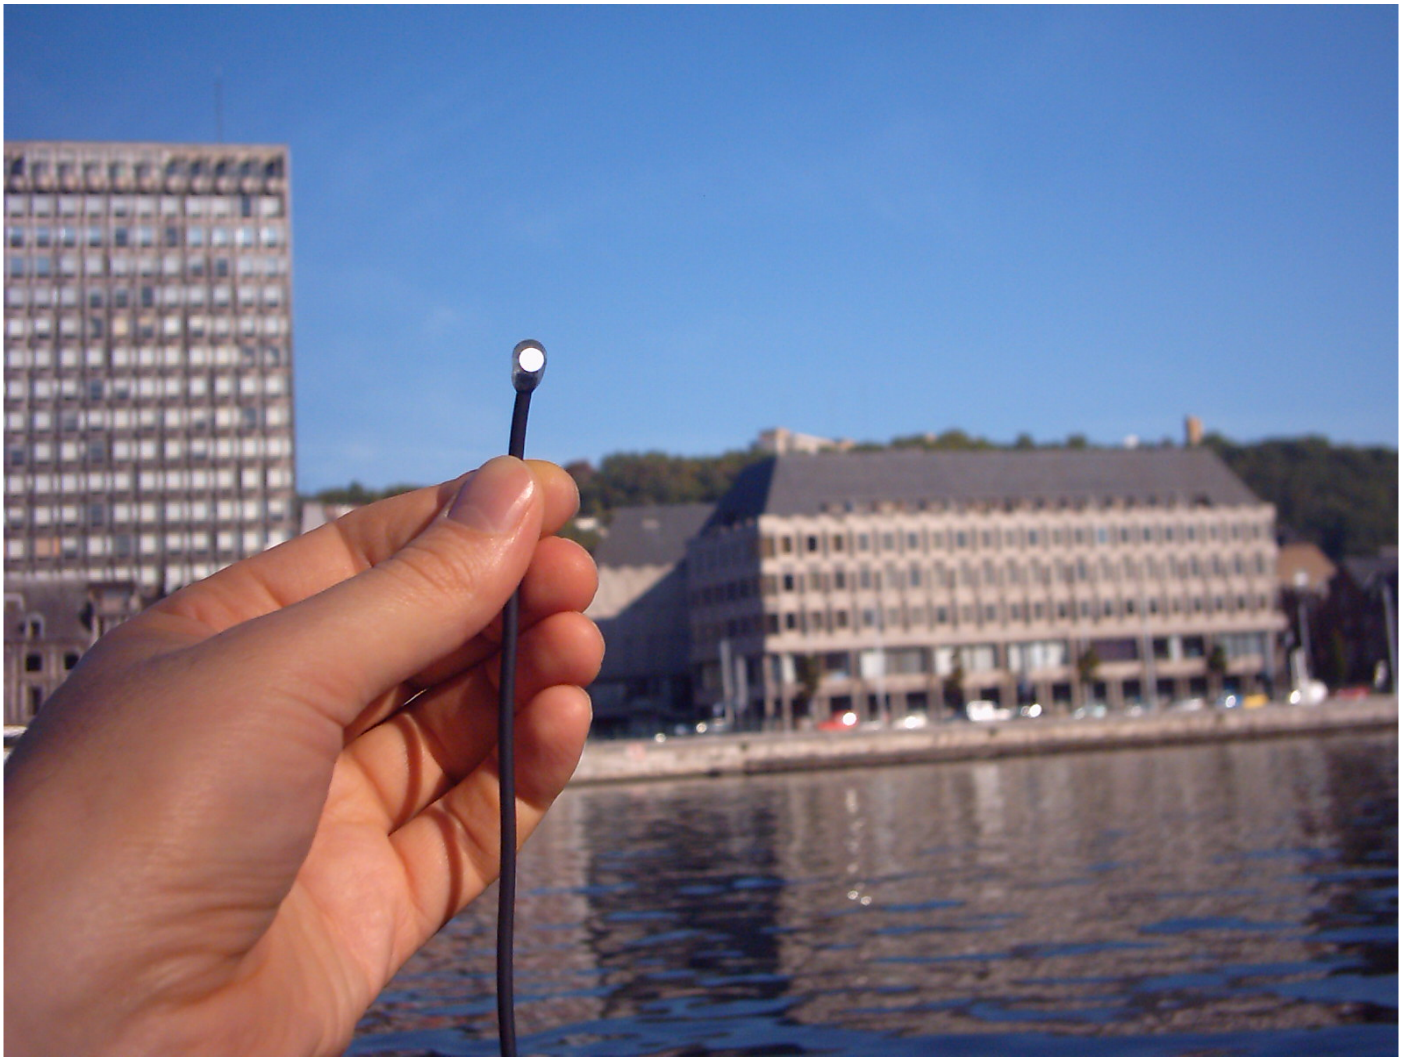
Powered by 000webhost

This didn't help anyway, so I invented another device: the "snake". The picture below shows six of them, an early version.



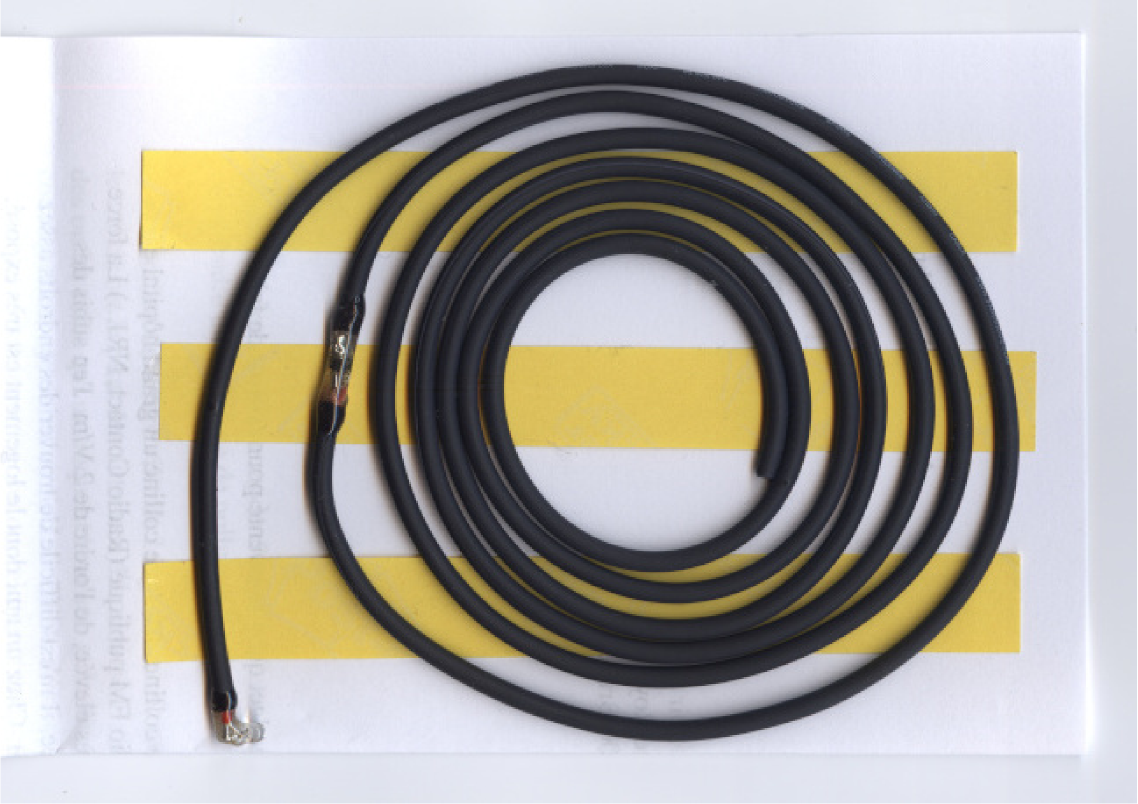
Powered by 000webhost

You just hang the snake in the flux of radio waves and the LED lamp at one end will bright up, clearly visible in daytime and enough to light and read a text at night.



The snake is less impressive than the calculator but it is much cheaper and easier to make and it can be sent in an envelope. I made tens of them and sent them to politicians, newspapers, universities... I gave some to local people, together with a user guide on a sheet of paper. Just like the calculator, the snake contains no battery. The lamp lights up solely on the power of the radio waves. The picture below shows a later version, that can be rolled up in an envelope that fits the conditions to be sent with only one stamp.

Powered by 000webhost



However mad it is to send such power on a city, nothing has been done yet against this. It's like an 19th century chemical plant sending its pollutants all around. Some complain but others argue that closing the factory would mean people laid off. Some then reply that being employed to feed children that die from ugly sicknesses may be nonsense... And so on, except for the fact that the chemical factory indeed had a purpose while the strength of the radio waves we're talking about, has no serious purpose at all.

Something common to all heavy sources of electromagnetic pollution is that it wouldn't cost much to make them harmless. For example, high tension power lines can be made harmless by feeding them DC current instead of AC current. This requires some more heavy electronics at the input and the output but the price of it is a detail in the whole. I studied the schematics of power saving lamps and simply noticed that they were conceived by people who do not understand the propagation of radio waves. Adding the necessary components to make the lamps radio-silent would almost not increase their prices. Enforcing proper norms will not change our way of life, it will just stop to favor the sociopathics amongst the industrials and lobbyists.

So, what can I do to help people understand the situation? They need to appropriate the scientific knowledge involved. Most assume that the necessary studies will be made by labs and then the governments will adapt the laws accordingly... That would be OK if it wasn't for the trillions of money involved. A minister in Belgium tried to prevent sugar dispensers in schools, she immediately got a made-up scandal on her shoulders. All she ultimately managed to get was to have some health advice notices glued on the sacred dispensers...

Flows of observations are now available, showing the effects of radio waves that match the norms: brains of rats destroyed, people unable to work, eggs that don't hatch, quarreling birds, increased risk of cancer, cows aging abnormally... I myself had seeds germinate and saw them die quicker when closer to a power saving lamp. Their strategy to cope with this is simple: "OK, there does exist scientific evidence of some danger... but there also does exist evidence that there is no danger at all! So let's balance the whole..." The norms are lowered but kept above what cell phone operators need for the current systems. The fact in itself of making a balance between scientific evidence is nonsense. Either a study proves a given danger and it can be verified, or bust. But anyway, what are those studies that tend to prove that there would be no danger? Lots of them are simply payed for by the cell phone industry... Yet some are perfectly serious, for example those concluding that radiations within the norms will not heat the brain or the body abnormally. This is perfectly true. There is no problem of scientific fairness involved with these studies. But, is a bullet harmless because it only very slightly heats your bones? A more sophisticated approach is to pick out studies that have borderline conclusions: "there may be a problem but it is not clear..." The study will be assumed to conclude that there is no problem at all, while it just was an inconclusive experiment like many are in science.

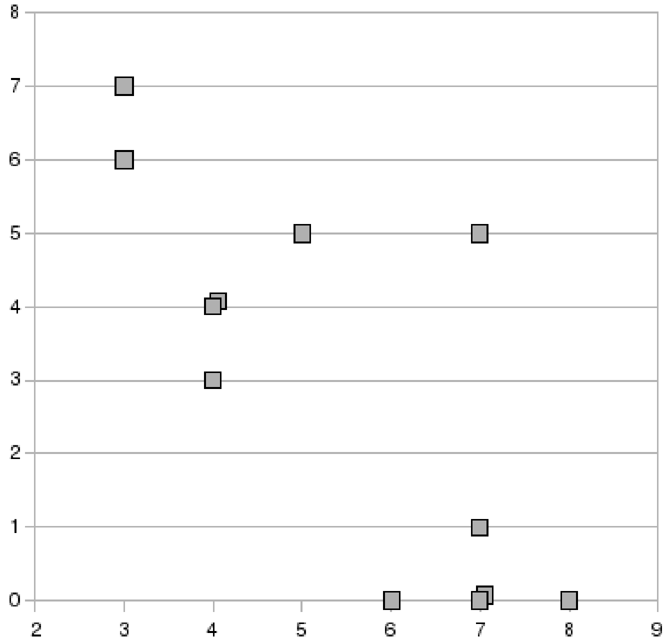
Powered by 000webhost

(When I'm exposed, I tend to compulsively perform simple tasks. What if a study examines if being exposed hampers the ability to perform that kind of tasks?)

Then, there is the problem that I'm going to make people sick. Indeed, electromagnetic hypersensitivity has a psychological component. Once people understand that they are victim to the radio waves and what symptoms the radio waves cause, they can overreact and become very sick when they start feeling the symptoms or just when they know there is a strong radiation force around. The radio waves induce a physiological stress, that hampers the proper functioning of the brain. When you add a psychological stress, due to the awareness of the problem, the summation of the two multiplies... Therapies for hypersensitive persons imply to dislearn them to overreact. Some friends of mine just refuse to start talking about electromagnetic sensitivity because they don't want to embark in the sickness. They do so with everything, meanwhile they eat very good food and have lots of pleasure in life. It works... with people with a strong health and a tad of selfishness.

When you are in a cold wind and you feel a pain in the neck, you know it is due to the wind and you take cover. Almost nobody can do this with the symptoms of an exposition to strong radio waves. You feel tired, some brain fog, like if your head was in a clamp, a headache, or simply you make stupid errors... You will blame yourself or the location, possibly the noisy people around... while in fact you are mainly undergoing electromagnetic sensitivity. The home of a friend is strongly exposed. After about twenty minutes I can nor more find my words and speak correctly, unless I wrap my head in aluminum foil. There is a fair chance that a while ago, I would have blamed my friend for being annoying (he is) to the point of making me speechless. There also is a fair chance that my friend is annoying because he hangs in that electromagnetic pollution everyday. Since he lives there, he became an alcoholic, lost his job, manages to keep no girlfriend... (Everything I mention here can have other causes. Quite often, such causes just add up. For example, the person blaming the noisy people around, would maybe have felt nothing if the noisy people weren't there. Like you don't feel your bad knee when you carry no bag.)

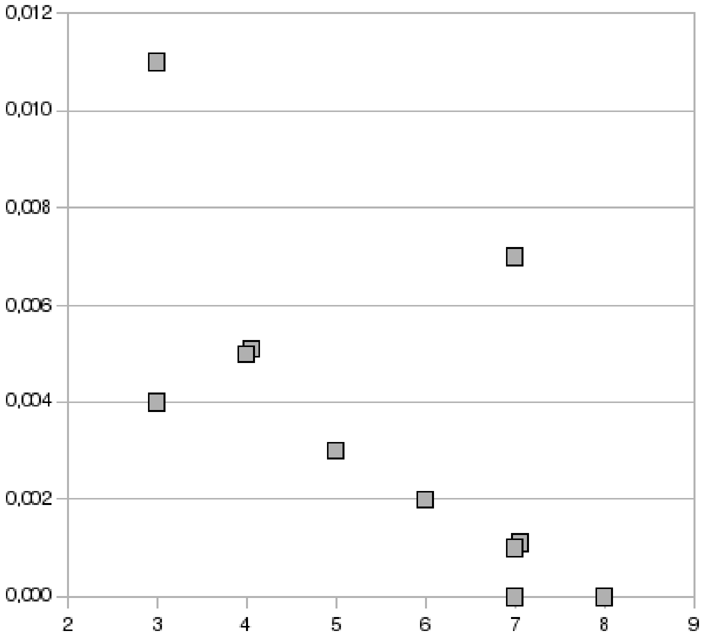
The impact of the electromagnetic pollution is severe. It is a far too heavy, and pointless, contribution to our burdens and losses. But how do you establish, scientifically, be it as an amateur, that there indeed is a problem? My initial approach can be an illustration of this. As my home is uninhabitable, I spend most of the day working in local libraries. I noticed that I could work quite well at some places and not at all at other places. Then I saw an article taped on a board, about the effects of cell phone and Wi-Fi radiations. Okay... I made a spreadsheet, with a row for each location and a note from 0 to 10 according to my ability to work there. Although I knew it was a weak approach, I then filled in each row the strength of the closest Wi-Fi router, as listed by my laptop. There was no correlation... but this proved not at all that the Wi-Fi was innocent. Weeks later I made a nonsensical but working little assembly that made the variability of the radio waves hearable. This time I got a correlation. Mild, but obvious. The ability to work is horizontally while the intensity of the radio signals is vertically:



It quickly became obvious that I was measuring no strong signal in the GHz bands. I had no doubt that there were cell phone and Wi-Fi emissions coming from all directions and echoing all around but their strength was obviously

Powered by 000webhost

weak. The problem was with lower frequencies. I accused the fluorescent lamps for a while, till I finally understood that there was only one strong source, hitting me everywhere; those 100 MHz public radio broadcasts. The picture below shows the final correlation. Only one dot disagrees with the theory:



I was heavily disturbed by the radio waves, simply unable to work, long before I started puzzling on the subject. This is a strong proof that the matter is not just psychological. Reciprocally, once I understood the psychological component, I tried to use it positively, to counterbalance the effects of the electrosmog. I did get some results but I was never able to work correctly in the most exposed places. It is by no means "just psychological". It is useless "to be willing to make a small effort". I did efforts that frightened other people. One thing that does clearly help is eating a lot of sugar (Organic jam on rice bread...) (by the way, is that why sugar dispensers are placed everywhere kids are supposed to think and learn, to counterbalance the effects of the nearby cell phone relay antennas?) Alcohol does also help and I'm afraid this is why people seem to become alcoholics in exposed habitations.

Also, it does sometimes happen that I feel like undergoing strong radio waves but when I pop out my measuring device, I measure nothing serious. I have a natural tendency to be knocked-out... The radio waves are far out my heaviest problem but they are not always responsible.

I started studying other sources of radio pollution. I had an obvious benefit of removing every power saving lamp in my home. I put ferrite cores on most power chords. On one power chord that I sometimes use to feed my laptop inside my shielded tent, I had to put ten ferrites till I felt no more direct effect. Something very interesting is that till then I had no problem when using my cell phone. You guessed correctly: I started having problems, to the point that I never more hold it against my ear. I always use an earplug linked to the cell phone by a wire with two ferrite cores. I suppose that since I started avoiding the exposure to strong radio waves (which significantly improved my life and ability to work), my brains are no more constantly knocked out. So they get knocked out if I hold my cell phone against my head. And I feel it. This is one more synergy between the public broadcasts emitters and the cell phone industry: one hides the other away. 'Want to prove that inhabitants close to a relay antenna are no worse than those further away? Do the experiment in a city that is strongly exposed to public broadcasts...

So: buy a measuring tool or have a friend assemble one for you. And start comparing your problems and those of the people around you, with the level of electromagnetic pollution. If you can, make large-scale experiments with tens of persons, under advice of somebody with knowledge in statistics (to build an expressive statistic yet completely false, is *easy*). We need many such experiments, till it becomes unbearable for local interlocutors to negate the problem and not to dim the emissions. Step by step, we need to conquer our world back. Some enterprises and some countries have already set their norms at responsible levels.

One very important parameter is the rate at which the problems build up and then disappear, when exposed. Some people claim that they instantly feel when their cell phone is going to ring. I never could verify this. A friend claims that his cat reacts when he is going to get a text message on his cell phone. I tried several times to see the cat change

Powered by 000webhost

behavior while making my cell phone emit close to him but I got nothing. So I suppose that the cat reacts to the tone of the cell phone and my friend brain-confuses the timing. (I don't pretend nobody can feel a text message arriving, I'm just saying that I never could verify.) What I'm sure about is that my problems need minutes to build up, most often some ten or twenty minutes, the problem possibly becoming really painful after an hour. Once the problem built up, it needs much more time to diminish, maybe four times more. I often had to sleep a whole night on it. One day I "burned" my brains by holding a very polluting power saving lamp about 3 decimeters away from my head. I only noticed the problem after half an hour. But then it was horrible, like if a flame had been sweeping inside my head. Really just like the ache of a burn wound. I had a strong nausea and headache, that calmed down only hours later. I identified a few persons whose problems are obviously due to the electromagnetic pollution, in all cases the same applies: it needs time to build up. This means you cannot simply walk in and out of an exposed zone and claim you feel no difference. Also, you cannot get into a safe zone and claim you feel no better. If you were already poisoned, you will stay that way a long while. The only sure approach is to stay really long in a safe zone, preferably spend the night there, then go working in a polluted area. Try to be aware of what happens to you. The next day go working in a safe zone and try to see the difference. (This is a goldmine to build inconclusive studies.)

Everybody is sensitive to electromagnetic waves. The question is about the level of the sensibility. That's why people who get seriously sick with the current levels of exposition are called "hypersensitive". They are more sensitive than the average, sometimes with very painful and debilitating consequences.

There is a whole ladder of symptoms. This is roughly the ladder for me, exposed to the 100 MHz FM broadcasts:

0.01	V/m	No problem
0.1	V/m	No more able to concentrate and work
1	V/m	head in a clamp, maybe difficulties to talk
10	V/m	Tried it once for 2 hours, had to stay the whole next day in bed with an awful headache.

The serious problems begin for me at 0.1 V/m. Yet I know some people that wouldn't be called hypersensitive and that get problems similar to mine at about 0.3 V/m. A friend spent with me the two hours under the 10 V/m radiation and claimed he endured no problem... but he made surprising errors on the way back. It is very difficult for me, in my city, to find locations where the force is around 0.01 V/m. Values between 0.1 and 0.3 are common. It is easy to find building with rooms reaching 1 V/m. The force is quite predictable, according to the location and the orientation of the building, how much it emerges out of other buildings... So, because many people are being affected and because the radiation is reasonably easy to measure or to estimate, making statistics linking common health problems with the level of exposition is quite doable.

Hypersensitive persons would be 1% of the population. The need to protect this minority is enough to stop those powerful broadcasts from reaching the ground. I don't understand why I have to add that everybody is being harmed, be it to a lesser degree. I met official people whose job is to help hypersensitive persons. They've seen their pain and anguish by themselves... but they feel clueless as to how to stop the emissions. It's a very strange situation, when even the people close to the steer and convinced of a problem, can't do anything to stop it.

It has been claimed that the hypersensitivity of some persons is caused by an accumulation of toxic metals or organic pollutants. In such cases, antioxidants can be of immediate help and detoxifications would greatly help. (Note that common medical analysis like looking for mercury and the like in samples of blood, urine or hair, will reveal nothing even under severe intoxication, because blood and hair renew constantly. Only a sudden intoxication can be revealed by such analysis. The toxics slowly accumulated in standing body cells like the brain... Best method seem to be to take a well-tuned quantity of chelating molecules and then perform an analysis of the blood or urine.)

Cell phone and Wi-Fi radiations are different, for several reasons: they don't spread the same way in the body, they are pulsated and their frequency make they will not target the same macromolecules in the body. It would seem that you need 3 times more force of FM broadcast waves than cell phone or Wi-Fi waves, to have a same global impact...

I was frightened when I understood that under those 2 V/m force of radiation, an electric current in the order of 1 mA oscillates through the body. Such a current at a high frequency of 100 MHz will interact with the body quite differently than a DC or low frequency AC current. You cannot make direct comparisons... Anyway, 100 mA of DC current can be enough to kill a person by electrocution. 1 mA of low frequency current is enough to feel the current as a tickle. What are the consequences of such a current on the chemical reactions in the liver, on the production of

Powered by 000webhost

hormones by glands everywhere in the body? What if the person being exposed is a pregnant woman, with the baby just at the worst place in the flux of current? The length of an "antenna" matters much to allow it to build up current. Teenagers have the "optimal" length for 100 MHz radio waves... One thing I'm sure about is that if the government decided that from now on the school kids will be latched electrodes on the body and a current of 1 mA send through several hours a day, whatever the frequency, the parents will not accept. But this *is* happening, through radio waves, and I could feel the neuroleptic-like effect of it. (By the way, this implies that those experiments that show brains of rats destroyed by cell phones waves within the norms, apply only to a lesser degree to human brains, because of the difference in size. Rats are close to the optimal length to be harmed by cell phone waves... The optimal wavelength to dammage teenagers is that of those 100 MHz public broadcasts...)

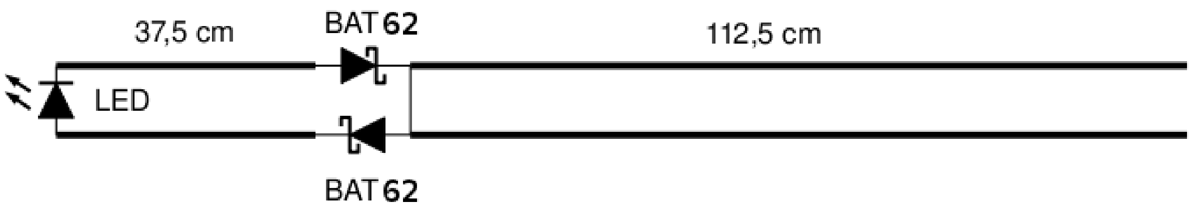
The radiations harm me more inside buildings than outside. I may get more sick under 0.2 V/m in a room than under 2 V/m directly exposed to an antenna. I don't know exactly why. Here are four possibilities:

- The roofs atop buildings act like prisms and send the waves towards the inhabitants beneath. Radio waves coming from above would be more harmful than when coming from aside.
- The radio waves resonate and echo inside the building and build up in metallic structures. This creates halos of proximity that will inject more power inside nearby living bodies. For example, while simply wrapping aluminum foil around my head, it is obvious that some designs of shielding will make me even more sick than using no aluminum at all. The same way, when some parts of the shielding of my tent wear off and stop to be conducting, I can get serious problems till I replace or complement the faulty area.
- Buildings contain their own sources of electromagnetic pollution. They add their effects to those of the pollution from the outside...
- Close to metallic structures, the electromagnetic field can become rotating. This because waves with equivalent strength come from different directions with different phase shifts.

Again, the four possibilities mentioned above are potentially very suitable to build experiments that demonstrate there is no problem. Perform the experiment in an anechoic place with the waves coming from aside and no other radiation than the one from the experiment... Just the opposite from real world situations but you can claim to be serious at avoiding parasitic variables...

If you want to find the FM emitters somewhere, fmscan.org is the reference I used till now.

This is the schematic of the "snake":



BAT62 detection diodes are no more produced. **BAT15** diodes work fine but they wear out; after a few months they stop functioning. **SMS7630** diodes are great but very little and mechanically fragile. **MMSD701T1G** diodes are sturdy and powerful; an excellent choice for a beginner. Such SMD diodes do also work for cell phone frequencies, which allows to test out a snake with a calling cell phone pushed against it. But any detection diodes that can manage 100 MHz will do.

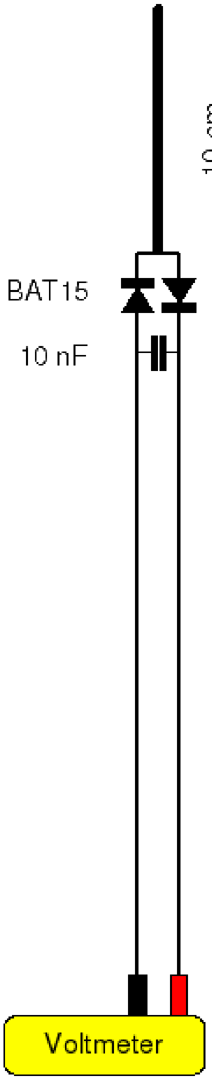
The LED I'm currently using is the **L-7113SEC-H** . It lights up with a low tension and a very low current (the bluer a LED, the more tension it needs). Its color is red yet close to orange hence it is easily seen by the human eye (the eye is most sensitive to green, yellow and orange). The beam is quite narrow so when the LED is directed towards somebody's eyes it will appear quite bright.

For the lengths of 37.5 and 112.5 centimeters, any electric wire with two copper conductors will do. Audio signal wire is a practical solution. Use the shielding as one of the two conductors. The lengths of the two segments must not be precise. What matters is that the total length of the snake be 1.5 meters. Do not hesitate to try out if a little

Powered by 000webhost

longer or shorter snake gives better results.

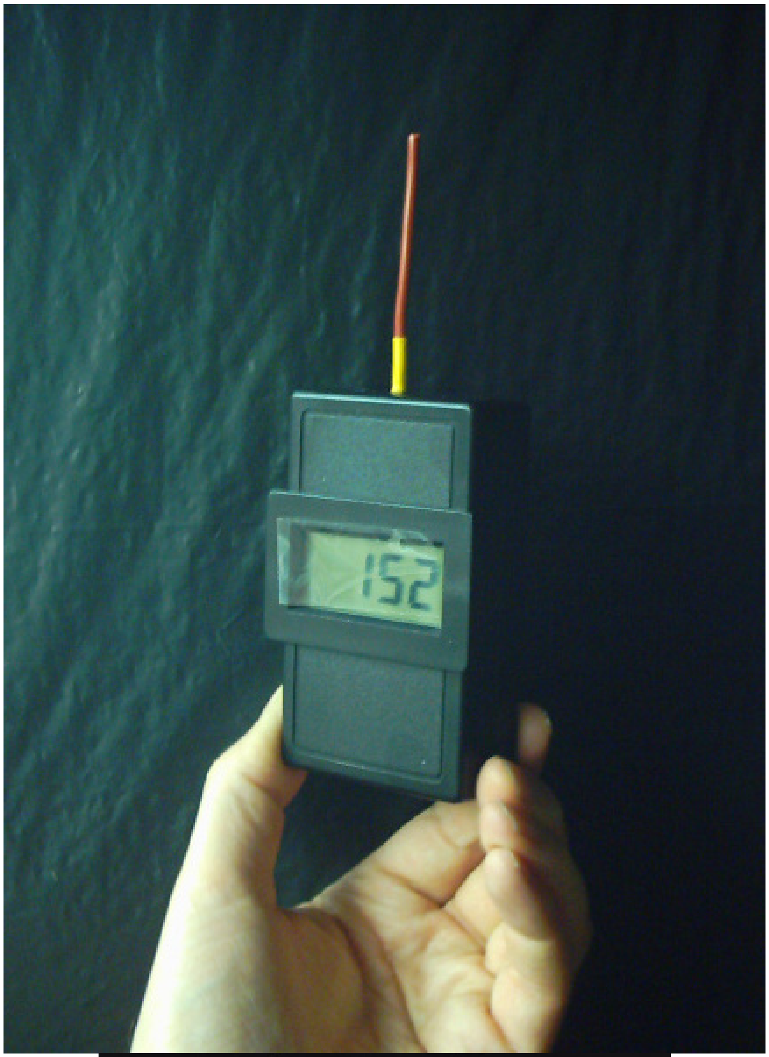
A schematic of my current probes, that I connect to a standard multimeter, measuring Volts DC. The measure displayed by the multimeter must be multiplied by 10. When using a 200.0 mV scale, just read while forgetting the dot:

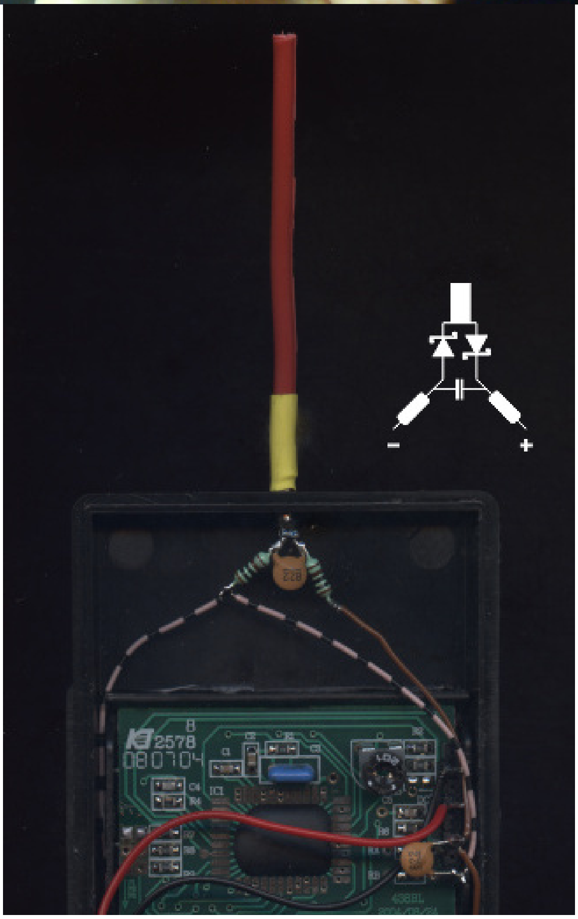


This is a picture of a device that tries to pack the whole in a neat gadget. The electronic circuit is a €7 digital Volts display with a scale of 200.0 mV. I soldered away the jumper that makes the dot be displayed. The antenna is only 7 cm long, so an RMS value is displayed (for roughly steady radio waves). The whole cost about €12. Hold the antenna perpendicular to the direction the waves come from and try to hold the device away from conducting objects like your body or metallic objects. You cannot closely trust such simple device yet it is very handy and adequate to compare the radiation level in different places:

Powered by 000webhost

Powered by 000webhost





Powered by 000webhost

Those probes and device, quite easily allow to know the direction some 100 MHz radiation come from. Hold the thing at some decimeters from your body, roughly at the height of the belly. Your body and the device form a directional antenna... When the device is towards the emitter, it will display up to twice the value, while when it is hidden from the emitter by your body, the measure will be very low.

If you measure something strong, yet by turning in different directions the device always shows approximately the same value, then you are probably undergoing low-frequency radio waves like short wave broadcasts.

If the emitter is close, like a power saving lamp or a wrongly build power supply, converge towards it simply using the fact that the closer you get, the stronger the measure.

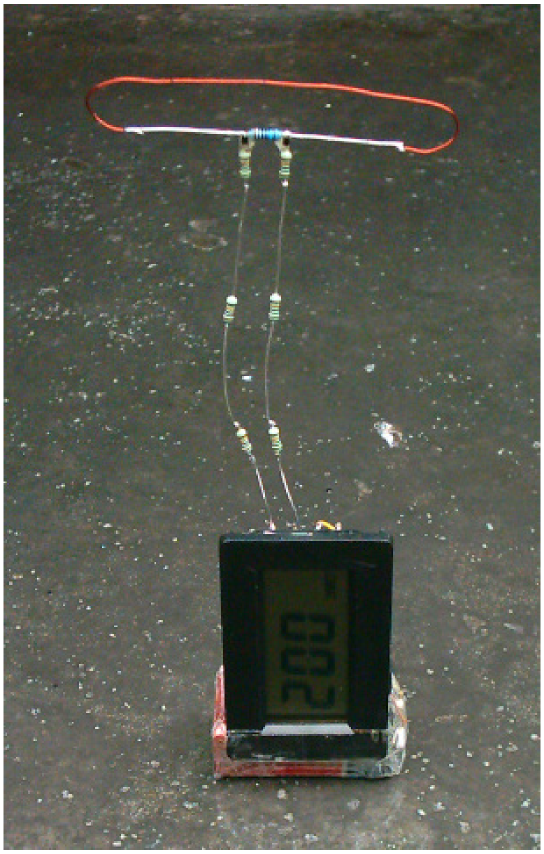
Such measuring tools are handy to find out power chords and appliances that pollute, yet then the measure displayed doesn't mean much. Once you are really close to an emitter, the measuring device and the emitter interact and the power flowing through the measuring device can be tremendous even though the device is only weakly polluting. You are in the "halo of proximity" of the device... Best example is most quality laptops, which emit almost no radio waves. I never could notice a problem while using my laptop when it is plugged to nothing... Yet if I hold a measuring tool against the screen I get frightening data... A few decimeters further, where my head can be, the measuring tool tells there is nothing... So, the high figures close to the laptop indeed tell that strong currents flow through it, but competent people made things such that those currents harm nobody...

If you want a global measure, away from the effects of your body, hold the device above your head. Or place it on some plastic or cardboard box and walk some distance away.

The windows are a common entry point of radio waves and electric wires can be awfull ducts, yet in some cases I noticed that metallic structures unrelated with electricity, like the copper tubes of water heating radiators, were the main ducts of radio pollution towards a room.

Below is a device I assembled to focus on 1.8 GHz cell phone radio waves. Close to the nearby cell phone relay antenna, in direct view of it, I could not measure much more than 0.1 V/m (pike value). While this is still too much, it is by no means comparable to the frightening 2 V/m intensity of the FM broadcasts. I also went measuring in places where people complain about problems similar to mine. They thought the reason was the nearby cell phone relay antennas. But I could measure no significant intensity of cell phone radio waves at all, while the force of the FM broadcasts was above 0.2 V/m...

Powered by 000webhost



After about a year experimenting, the most simple protection I could come up with against 100 MHz broadcasts is a headband of aluminum, much the shape and size of a sweatband. I hide it inside a bonnet. I have no idea as to how and why it helps, aside from the general fact that any conducting structure will change something to the propagation of high frequency currents. Don't make it too high, a 3 to 4 centimeters height is OK. To try this out, you can just fold in a circle a 1 meter long wrap of aluminum and compress it to a flattened ring that fits your head. If you intent to re-use it, then you must strengthen it with lengths of tape before (inside) and after (outside) the ring is constituted. Make sure the tape does not hamper a perfect electric contact all around the ring. This protection is not perfect but it really helps.
When the field strength is above 0.1 V/m, I need a complementary vertical band in order to be able to work.
This also is a cheap way to make statistics. Compare days with the headband to days without the headband. In order to be scientific, you must ask somebody else to put the headband inside your bonnet every morning, at random. Every morning, the other person writes down if there was a conducting headband inside the bonnet or not. Every evening, you write a comment down to how your day was (headache? brain fog? errors? doomed day?) Then after a while you compare the two. At worst, if you have to do it alone, buy two identical bonnets, push a plastic headband inside one and an aluminum headband inside the other, and spend each day without knowing which one you picked. At the end of the day, write your appreciation down before checking and writing down which bonnet you picked.

A friend who is a physician points out that in many administrations, be they public or private, the employees are being persecuted. (That often happens when the work done by the administration is mostly useless and only serves to justify the social position and the salaries of a few people.) A statistic about the health impact of radio waves in such administrations could be of few significance, because the people have all kinds of health problems due to the harassment. The addition to this by the radio waves may be comparatively negligible. (Yet another way to build a statistic that shows few or no impact of the radio waves: perform it in a place where people bow under humilations...)

I was quite frightened to discover that the symptoms caused by radio waves, as I see them around me, are very close to those of "radiation poisoning". This is part of nuclear medicine. When a victim is exposed to a short and strong burst of radioactivity or any other ionizing radiation, its body will quickly react like if it had been poisoned. A "low" poisoning by radiations yields headaches, tiredness, difficulties to think... while stronger poisoning can lead to the person die in a few days like if it was heavily burn. The exposure to ionizing radiations is measured in "Gray". 1 Gy leads to a low poisoning. So I computed out how much energy a person gets from the local FM emitter, like the person I know that get sick at their desk. The result is 0.01 Gy for 8 hours of exposition, which is quite close.

Radio waves can induce all the typical problems caused by that ionisinig radiations but the energy levels involved can be quite different. For example, ionizing radiations cause burns without increasing the temperature of the body, while radio waves can only burn if they are powerful enough to heat the body. Radio waves can induce cancer but again the energy required is ways higher, like spending ten years using a cell phone against the head, several hours a day.

Body cells can be attacked by all kinds of means. Ionizing radiations lead to direct damage of the cell membrane. Radio waves disturb the molecular cell gates operate. The cell will always react the same way, as for poisoning: it will close the cell gates, to try to shun itself from the outside world and from the harm. This has many consequences. The cell is less able to fulfill its purpose inside the body. It uses resources to try to protect its internal parts. It will accumulate waste. That's why people get tired, less efficient or even sick. When the aggression made to the cell is deemed too strong, the cell will auto-destruct. That's the way radiations and chemicals can be used against cancer, making the cancer cell suicide.

The cells can be helped to better recover from the state of shock. Also they can be made to go less likely into the state of shock. Medication and health advice can be helpful for this.

A link has been proposed between autism and radio pollution. The growth of the human brain is very complex, with cells traveling from one side of the brain towards the other to find their place. This involves a tremendous amount of communication and coordination between the cells. What if those cells are too often put into a state of shock?

ABSTRACT

This paper presents the RF energy harvesting module (RECTENNA). The working range of this module includes multiple bands i.e. GSM, ISM, WLAN, and UWB band. To enhance the capturing RF power capability an array arrangement of coplanar monopole antenna has been proposed. Wilkinson power combiner has also been implemented to combine the powers of this antenna array. The RF-DC converter circuit having seven stages has also been integrated with this structure. This module produces the DC voltage of 1.8 V with respect to + 40 dB RF input. It is the unique module because it has no need of port connectors. The impedance matching of antenna and converter has been fulfilled by incorporating the passive component at the combiner's branch. The value of this passive component is kept equal to the existing value of impedance at input port of converter circuit.

Key words: *Rectenna, coplanar monopole antenna, Wilkinson power combiner, antenna array, impedance matching, RF-DC converter circuit.*

I. INTRODUCTION

The primary focus of the Rectenna circuit is to design a suitable RF receiving antenna. For this purpose, an antenna should be designed to resonate on single, dual and multiband frequencies according to the need of the applications. The main aim of proposed work is to design a RF energy harvesting module for a wide range of frequencies which covers most of functional bands, e.g. GSM, Radio, ISM and UWB. It is well known that the RF spectrum widely employed for 900 MHz – 2 MHz (television and radio applications, GSM), 2.1GHz - 2.6 GHz (ISM band for various applications), and 3.1GHz -10.6 GHz (ultra wideband for satellite applications) [1]. Narrow band systems such as WLAN (3.1GHz - 4.4GHz), HIPERLAN (5.1GHz - 5.3GHz), C-BAND (4.4GHz - 5GHz) are also the useful bands. Keeping this in mind a compact coplanar monopole antenna has been designed and its 2 X 2 arrangement was reported [2]. For preparing the array arrangements of the antenna the literature [3-5] were profoundly studied.

This antenna works for the wide range of frequencies of the above specified bands. As reported in the structure [2] the Wilkinson power combiners were preferred because it accomplishes two essential tasks of the structure. Firstly it combines the powers of two or four antennas serially and increases the input power of RF-DC converter circuit of energy harvesting module. Secondly it considered as the element of afford, for the impedance matching of antenna port and converter circuit. The maximum power transfer concept has been chosen for this impedance matching.

The multi band operation of the RF energy harvesting module developed on a single substrate is the innovation of this paper.

II. ANTENNA DESIGN

In RF energy harvesting module antenna is the major functionary part. It receives the power from the electromagnetic spectrum. The received RF power is converted into the DC output voltage from the module. So the antenna should be capable enough to receive the maximum energy/power from the spectrum. As the working range of our design is preferred from 900 MHz -10 GHz, the modification in the monopole antenna structure for multi frequencies resonance has investigated. For increasing the area of receiving as well as gain of the structure the 2 x 2 array of the coplanar monopole antenna has been designed and presented [2]. In this paper [2] only the simulated results were presented. The simulated antenna structure was as shown in figure 1[2]. The power of the individual structure has been combined by the Wilkinson power combiner. The reason for selecting this combiner is that we may externally adjoin the surface mount components at the combining branch of it for impedance matching purpose.

Figure 1. Simulated structure of 2 x 2 array arrangement of coplanar monopole antenna [2].

The simulated structure from licensed software HFSS version16 has been exposed resonant on the multi frequencies of different allocated bands as 900 MHz and 1.75 GHz (GSM band) 2.7 GHz (ISM), 3.5 GHz, 4 GHz and 5.2 GHz (WLAN), 6.5 GHz, 7.4 GHz, 8.5 GHz and 10 GHz (UWB).

Further in this paper all measured results have been reported for the validation of proposed antenna structure. For the measurement purpose proposed structure has been fabricated as shown in figure 2. The measured result of return loss from VNA (Keysight Technologies) for fabricated structure is shown in figure 3. The resonant frequencies of the fabricated structure has exposed on 900 MHz (GSM), 1.29 GHz (ISM), 4.1 GHz and 5.6 GHz (WLAN), 6.8 GHz and 9 GHz (UWB), that is the almost same as simulated result of the structure reported earlier [2].

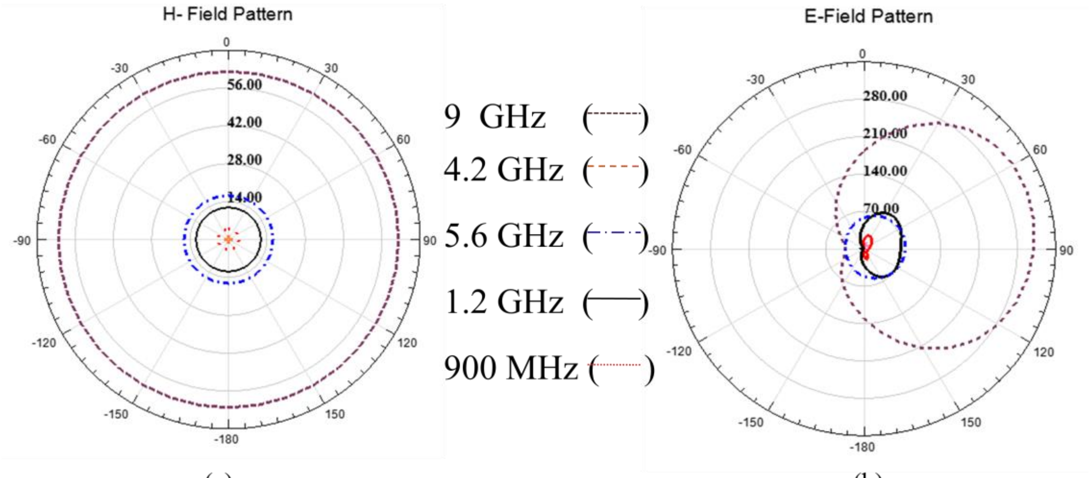
The measured H- field patterns for these frequencies are shown in figure 4(a) and E-field patterns are shown in figure 4 (b). These patterns show that the antenna supposed to be worked as omnidirectional.



(a) (b)

Figure 4. (a) H- field pattern (b) E- field Pattern

III. RF-DC CONVERTER

The RF-DC converter circuit is also the important part of energy harvesting module. The output of harvester circuit is the DC voltage. The input of this module is the magnitude of AC voltage at the antenna port. This AC voltage is proportional to the captured power on the antenna from the RF spectrum. In this paper for energy conversion purpose a voltage doubler circuit has been used. The number of stages of the converter circuit may be increased for escalating the DC output voltage value. The relation of number of stages (n) and output voltage ($V_{o/p\ volt}$) of converter circuit is considered as

$$V_{o/p\ volt} = \frac{nV_{o/p\ volt}}{nR_0 + R_L} R_L$$

In this paper conversion design contains seven numbers of stages of Villard voltage doubler circuit. The main function of this conversion circuit is to convert the RF harvested energy from the ambient into the direct current (DC) voltage. This seven stage Schottky diode voltage doubler circuit is first designed, modelled and simulated on ANSYS RF circuit designer and then fabricated and tested. After that, this circuit has integrated with the same substrate of antenna. The converter circuit in this design uses zero bias Schottky diode (SMS7621-001-SOT23) from Skyworks. The simulated design of seven stage RF-DC converter circuit has been presented for this purpose [6]. The simulated DC output voltage at the first stage and seventh stage of RF-DC converter circuit from the RF circuit simulator was as 48.2 mV and 289.6 mV respectively. The fabricated circuit of seven stage RF-DC converter and its analysis has already been presented [6]. So in this paper we implemented that designed RF-DC circuit (having seven stages) [6] with the same single substrate of designed antenna array.

IV. RF ENERGY HARVESTING MODULE

This part of paper presented a RF energy harvesting module on a single substrate working on multi bands of the frequency range 900 MHz to 10 GHz. The DC output from the multiband harvesting circuit has been presented it produces 3.4 V DC output [8]. The motive of this part is to design whole module on a single substrate for a wide range of operation and should be able to produce the DC output voltage of the value more than 1.5 V from the ambient RF spectrum. This DC voltage may be boosted by adding the booster circuit. In addition to the structure on a single substrate of RF module, it is also proposed that any value of impedance measured at the converter circuit input impedance may be matched to antenna port by using SMD (Surface mount device) resistor components. This is possible only due to the use of Wilkinson power combiner implemented at the antenna structure. No need of matching of connectors impedances. So it may be called connector-less module. This is the uniqueness of the structure.

The novel idea of impedance matching is that; for any wilkinson power combiner a given number of output ports N, an input impedance R_S and output load impedance R_L, and the characteristic impedance of each quarter-wave section, $Z_{\lambda/4}$, is given by

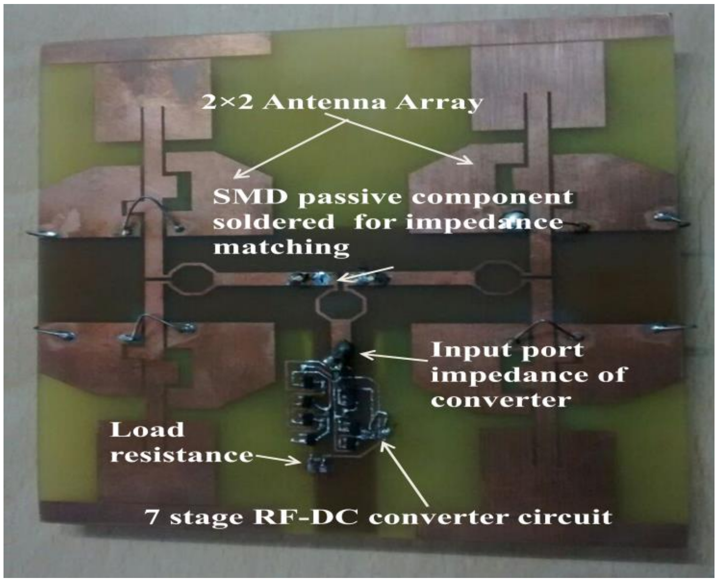
$$Z_{\lambda/4} = \sqrt{N\, R_L R_S}$$

Additionally

$$R = R_L$$

the resistor (R) that connect between the common junction and the output ports are simply equal to the load impedances (R_L) at each output. Now considering the input impedance of RF-DC converter circuit as the value of load resistance (R_L) of the output of the Wilkinson power combiner. This impedance has been measured by vector network analyzer. The SMD resistor of this measured value (R) has been mounted in between the combining leg of Wilkinson power combiner. In this way we can easily match the impedance of antenna and converter circuit. This satisfies the condition of maximum power transfer.

The fabricated RF energy module on a single substrate with impedance matching arrangement is shown in figure 5. The seven stage RF-DC converter has been implemented by the combination of seven Schottky diodes and seven capacitors. The load resistance and source resistance has also been added into the circuit. The overall size of the module is 124 x 102 mm^2.



2×2 Antenna Array
SMD passive component soldered for impedance matching

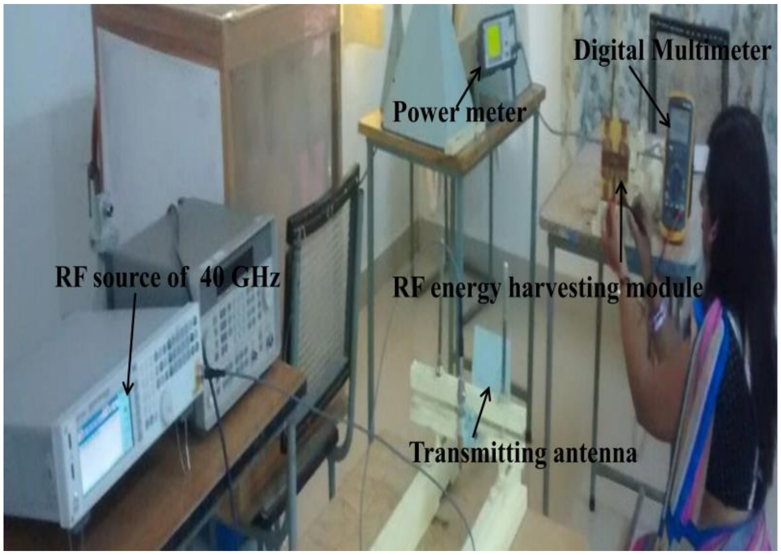
7 stage RF-DC converter circuit

Figure 5. Fabricated RF energy harvesting module integrated on a single substrate.

The measurement with module in RF lab has been shown in figure 6. The measurement has taken at ICRS (International center for Radio Science) lab, Jodhpur. Rajasthan, INDIA. The RF source is of 40 GHz. First of all with respect to the source on the resonant frequencies of the module; power received at the antenna port has been measured on the power-meter.



Digital Multimeter

RF source of 40 GHz
RF energy harvesting module
Transmitting antenna

Figure 6. Measurement of output DC voltage from the module with respect to RF input voltage from RF source.

The DC output voltage at the module output with respect to RF input power varying from - 40 dB m to + 40 dB m has been plotted for five resonant frequencies (900 MHz, 1.2 GHz, 4.1 GHz, 5.6 GHz and 9 GHz). The plot of the data is as shown in figure 7. The maximum DC output is 1.823 V.

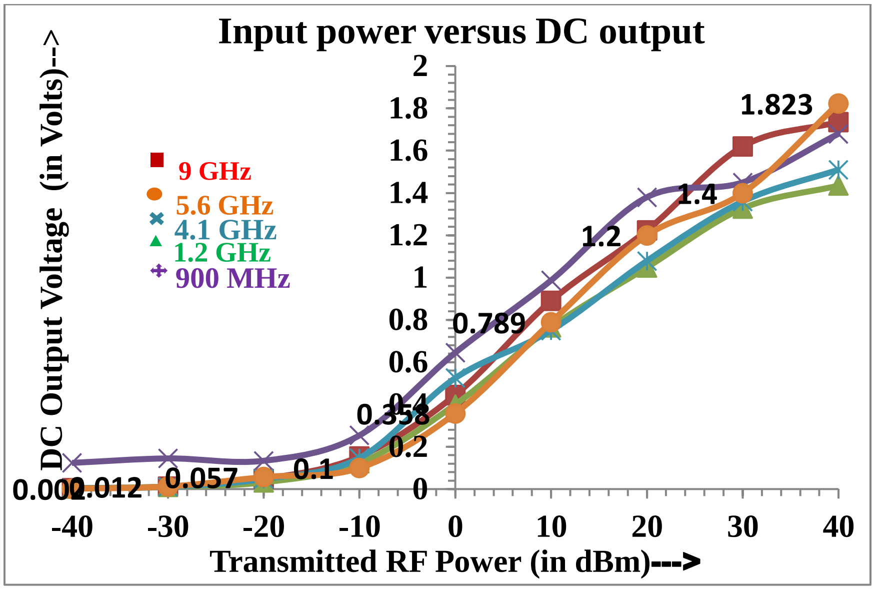

Figure 7. The transmitted RF input power versus DC output at the module graph.

The conversion efficiency (in %)of the module is calculated by the formula

$$\eta = \frac{V_{DC\ output}}{V_{input}} \times 100$$

The $V_{DC\ output}$ is the output measured by the digital multimeter and V_{input} is the magnitude of the input voltage at RF power source. The efficiency for the 9 GHz frequency is shown in the figure 8. As shown in figure the efficiency increases as the RF power increases.

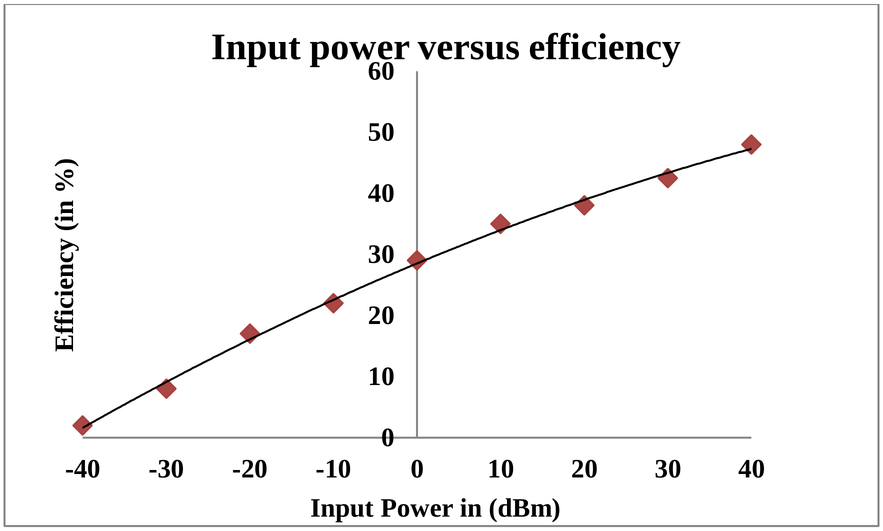

Figure 8. Input RF power versus efficiency graph.

The efficiency increases by the change in load resistance. For the input RF power +10 dBm the change in efficiency with respect to the change in load resistance is shown in figure 9. The maximum DC output voltage (1.823 V) for +40 dBm has been noted on the load resistance 22 k-ohms.

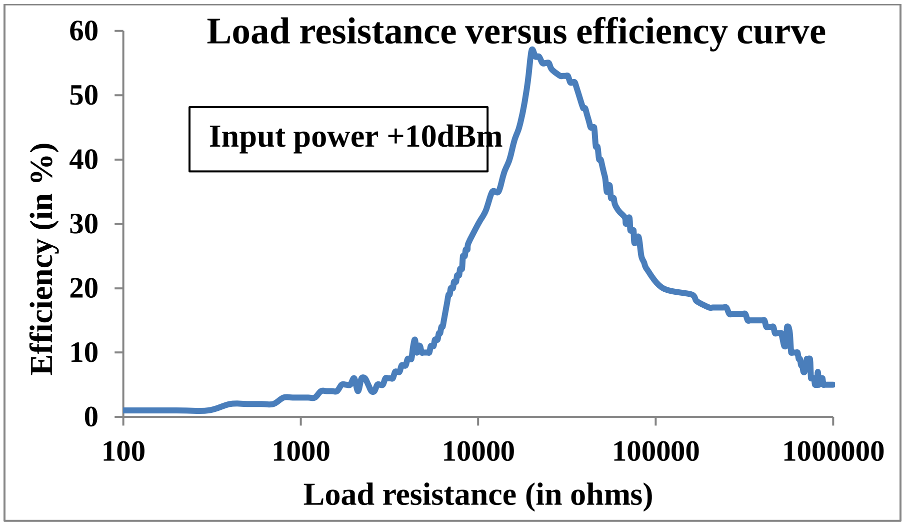

Figure 9. The load resistance versus efficiency curve.

V. CONCLUSION

A novel RF energy harvesting module has been presented in this paper. The antenna for this module has the structure of 2×2 array of the coplanar monopole antenna. The novelty which is proposed lies in the fact that a seven stage RF-DC converter circuit has been integrated on the same substrate of antenna. This makes the module connector-less. Another uniqueness of this module is that the impedance between the antenna and the converter circuit is matched by using the maximum power transfer concept. The Wilkinson power combiners have been specifically selected for this purpose as they combine the powers of antenna arrays. For impedance matching between the antenna output port and RF-DC converter port, the existing input impedance at the input port of the converter circuit is measured. And the component of that measured value has been mounted at the Wilkinson combining branch. This arrangement reported the matching between the antenna and circuit ports. The DC output of the module has been measured. The maximum DC output is 1.823 V with respect to +40 dB m input RF power, with the load resistance 22 k ohm for the frequency 9 GHz. This voltage may be boosted by integrating a booster circuit. The voltage may be increased by using the super capacitor at the output of module.

VI. ACKNOWLEGEMENT

The authors are thankful to our Institutes Swami Keshvanand Institute of Technology, Management and Gramothan, Jaipur and Malaviya National Institute of Technology Jaipur, Rajasthan, India for providing the licensed software and fabrication facilities. The authors are also thankful to Dr. O. P. N Calla, Director- ICRS (International Center for Radio Science) lab, Jodhpur, Rajasthan, India for providing the measurement facilities.

The author(s) declare(s) that there is no conflict of interest regarding the publication of this paper.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

APPARATUS FOR TRANSMITTING ELECTRICAL ENERGY.

1,119,732. Specification of Letters Patent. **Patented Dec. 1, 1914.**

Application filed January 18, 1902, Serial No. 90,245. Renewed May 4, 1907. Serial No. 371,817.

To all whom it may concern:

Be it known that I, Nikola Tesla, a citizen of the United States, residing in the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Apparatus for Transmitting Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.

In endeavoring to adapt currents or discharges of very high tension to various valuable uses, as the distribution of energy through wires from central plants to distant places of consumption, or the transmission of powerful disturbances to great distances, through the natural or non-artificial media, I have encountered difficulties in confining considerable amounts of electricity to the conductors and preventing its leakage over their supports, or its escape into the ambient air, which always takes place when the electric surface density reaches a certain value.

The intensity of the effect of a transmitting circuit with a free or elevated terminal is proportionate to the quantity of electricity displaced, which is determined by the product of the capacity of the circuit, the pressure, and the frequency of the currents employed. To produce an electrical movement of the required magnitude it is desirable to charge the terminal as highly as possible, for while a great quantity of electricity may also be displaced by a large capacity charged to low pressure, there are disadvantages met with in many cases when the former is made too large. The chief of these are due to the fact that an increase of the capacity entails a lowering of the frequency of the impulses or discharges and a diminution of the energy of vibration. This will be understood when it is borne in mind, that a circuit with a large capacity behaves as a slackspring, whereas one with a small capacity acts like a stiff spring, vibrating more vigorously. Therefore, in order to attain the highest possible frequency, which for certain purposes is advantageous and, apart from that, to develop the greatest energy in such a transmitting circuit, I employ a terminal of relatively small capacity, which I charge to as high a pressure as practicable. To accomplish this result I have found it imperative to so construct the elevated conductor, that its outer surface, on which the electrical charge chiefly accumulates, has itself a large radius of curvature, or is composed of separate elements which, irrespective of their own radius of curvature, are arranged in close proximity to each other and so, that the outside ideal surface enveloping them is of a large radius. Evidently, the smaller the radius of curvature the greater, for a given electric displacement, will be the surface-density and, consequently, the lower the limiting pressure to which the terminal may be charged without electricity escaping into the air. Such a terminal I secure to an insulating support entering more or less into its interior, and I likewise connect the circuit to it inside or, generally, at points where the electric density is small. This plan of constructing and supporting a highly charged conductor I have found to be of great practical importance, and it may be usefully applied in many ways.

Referring to the accompanying drawing, the figure is a view in elevation and part section of an improved free terminal and circuit of large surface with supporting structure and generating apparatus.

The terminal D consists of a suitably shaped metallic frame, in this case a ring of nearly circular cross section, which is covered with half spherical metal plates P P, thus constituting a very large conducting surface, smooth on all places where the electric charge principally accumulates. The frame is carried by a strong platform expressly provided for safety appliances, instruments of observation, etc., which in turn rests on insulating supports F F. These should penetrate far into the hollow space formed by the terminal, and if the electric density at the points where they are bolted to the frame is still considerable, they may be specially protected by conducting hoods as H.

A part of the improvements which form the subject of this specification, the transmitting circuit, in its general features, is identical with that described and claimed in my original Patents Nos. 645,576 and 649,621. The circuit comprises a coil A which is in close inductive relation with a primary C, and one end of which is connected to a ground-plate E, while its other end is led through a separate self-induction coil B and a metallic cylinder B′ to the terminal D.

The connection to the latter should always be made at, or near the center, in order to secure a symmetrical distribution of the current, as otherwise, when the frequency is very high and the flow of large volume, the performance of the apparatus might be impaired. The primary C may be excited in any desired manner, from a suitable source of currents G, which may be an alternator or condenser, the important requirement being that the resonant condition is established, that is to say, that the terminal D is charged to the maximum pressure developed in the circuit, as I have specified in my original patents before referred to. The adjustments should be made with particular care when the transmitter is one of great power, not only on account of economy, but also in order to avoid danger. I have shown that it is practicable to produce in a resonating circuit as E A B B′ D immense electrical activities, measured by tens and even hundreds of thousands of horse-power, and in such a case, if the points of maximum pressure should be shifted below the terminal D, along coil B, a ball of fire might break out and destroy the support F or anything else in the way. For the better appreciation of the nature of this danger it should be stated, that the destructive action may take place with inconceivable violence. This will cease to be surprising when it is borne in mind, that the entire energy accumulated in the excited circuit, instead of requiring, as under normal working conditions, one quarter of the period or more for its transformation from static to kinetic form, may spend itself in an incomparably smaller interval of time, at a rate of many millions of horse power. The accident is apt to occur when, the transmitting circuit being strongly excited, the impressed oscillations upon it are caused, in any manner more or less sudden, to be more rapid than the free oscillations. It is therefore advisable to begin the adjustments with feeble and somewhat slower impressed oscillations, strengthening and quickening them gradually, until the apparatus has been brought under perfect control. To increase the safety, I provide on a convenient place, preferably on terminal D, one or more elements or plates either of somewhat smaller radius of curvature or protruding more or less beyond the others (in which case they may be of larger radius of curvature) so that, should the pressure rise to a value, beyond which it is not desired to go, the powerful discharge may dart out there and lose itself harmlessly in the air. Such a plate, performing a function similar to that of a safety valve on a high pressure reservoir, is indicated at V.

Still further extending the principles underlying my invention, special reference is made to coil B and conductor B′. The latter is in the form of a cylinder with smooth or polished surface of a radius much larger than that of the half spherical elements P P, and widens out at the bottom into a hood H, which should be slotted to avoid loss by eddy currents and the purpose of which will be clear from the foregoing. The coil B is wound on a frame or drum D¹ of insulating material, with its turns close together. I have discovered that when so wound the effect of the small radius of curvature of the wire itself is overcome and the coil behaves as a conductor of large radius of curvature, corresponding to that of the drum. This feature is of considerable practical importance and is applicable not only in this special instance, but generally. For example, such plates at P P of terminal D, though preferably of large radius of curvature, need not be necessarily so, for provided only that the individual plates or elements of a high potential conductor or terminal are arranged in proximity to each other and with their outer boundaries along an ideal symmetrical enveloping surface of a large radius of curvature, the advantages of the invention will be more or less fully realized. The lower end of the coil B—which, if desired, may be extended up to the terminal D—should be somewhat below the uppermost turn of coil A. This, I find, lessens the tendency of the charge to break out from the wire connecting both and to pass along the support F.

Having described my invention, I claim:

1. As a means for producing great electrical activities a resonant circuit having its outer conducting boundaries, which are charged to a high potential, arranged in surfaces of large radii of curvature so as to prevent leakage of the oscillating charge, substantially as set forth.

2. In apparatus for the transmission of electrical energy a circuit connected to ground and to an elevated terminal and having its outer conducting boundaries, which are subject to high tension, arranged in surfaces of large radii of curvature substantially as, and for the purpose described.

3. In a plant for the transmission of electrical energy without wires, in combination with a primary or exciting circuit a secondary connected to ground and to an elevated terminal and having its outer conducting boundaries, which are charged to a high potential, arranged in surfaces of large radii of curvature for the purpose of preventing leakage and loss of energy, substantially as set forth.

4. As a means for transmitting electrical energy to a distance through the natural media a grounded resonant circuit, comprising a part upon which oscillations are impressed and another for raising the ten-

sion, having its outer conducting boundaries on which a high tension charge accumulates arranged in surfaces of large radii of curvature, substantially as described.

5. The means for producing excessive electric potentials consisting of a primary exciting circuit and a resonant secondary having its outer conducting elements which are subject to high tension arranged in proximity to each other and in surfaces of large radii of curvature so as to prevent leakage of the charge and attendant lowering of potential, substantially as described.

6. A circuit comprising a part upon which oscillations are impressed and another part for raising the tension by resonance, the latter part being supported on places of low electric density and having its outermost conducting boundaries arranged in surfaces of large radii of curvature, as set forth.

7. In apparatus for the transmission of electrical energy without wires a grounded circuit the outer conducting elements of which have a great aggregate area and are arranged in surfaces of large radii of curvature so as to permit the storing of a high charge at a small electric density and prevent loss through leakage, substantially as described.

8. A wireless transmitter comprising in combination a source of oscillations as a condenser, a primary exciting circuit and a secondary grounded and elevated conductor the outer conducting boundaries of which are in proximity to each other and arranged in surfaces of large radii of curvature, substantially as described.

9. In apparatus for the transmission of electrical energy without wires an elevated conductor or antenna having its outer high potential conducting or capacity elements arranged in proximity to each other and in surfaces of large radii of curvature so as to overcome the effect of the small radius of curvature of the individual elements and leakage of the charge, as set forth.

10. A grounded resonant transmitting circuit having its outer conducting boundaries arranged in surfaces of large radii of curvature in combination with an elevated terminal of great surface supported at points of low electric density, substantially as described.

TESLA AGAINST MARCONI

The Dispute for the Radio Patent Paternity

Paul Brenner, *M.Sc., Senior Member, IEEE, Member WREN, Israeli Representative in the World Renewable Energy Council*

Abstract: **The goal of this paper is to present the multilateral personality of the greatest inventor in history, Nikola Tesla and the claims against Guglielmo Marconi for the radio patent paternity.**

Index Terms: **Tesla (T.), Marconi (M.), coherer, magnifying transformer, LW (long wave), SW (short wave), MW (medium wave).**

I. INTRODUCTION:

A genius is born - Nikola Tesla [1]

Fig. 1.Nikola Tesla at the age of 23. *(Courtesy of Wikipedia)*

Nikola Tesla (Fig.1) saw the daylight for the first time in his life in Smiljan, a small village in Croatia, in the Lika region, on July 10, 1856. His father, Rev. Milutin Tesla was a priest in the Serbian Orthodox Church Metropolitanate of. Sremski Karlovci and his mother, Ana Kalinić, a very talented home craft tools producer, never learned to read, although she was able to recall from memory entire epopees. After the school in Gospić, where he finished a 4 year term in only 3, T. started in 1875 to learn electrical engineering at the Austrian Polytechnic in Graz. Despite the affirmations of some sources, there are no precise indications if he received his Baccalaureate degrees from the university at Graz, since this university declared that he did not receive any title and did not continue his study after the first semester of the third year [1]. In December 1878 he left Graz, breaking also all relationships with his family. Some friends thought that he had drowned in Mura. What is known is that T.was employed for a year as assistant engineer in Maribor, Slovenia, where he suffered a nervous breakdown. Persuaded by his father to continue his studies, he attended the Charles-Ferdinand University in Prague in 1880, where he received the strong influence of Ernst Mach. However, he did not finish his study and left the university after the death of his father, completing a term of only 1 year. But he was genial, even without an academic title. Tesla was an autodidact. He started to read many works, memorizing whole books. Specialists supposed that T. had a photographic memory. In his autobiography he tells that many times he experienced detailed moments of inspiration. Since his childhood, T. was stricked by halucinations accompanied frequently by blinding flashes of light. Much of the effects of this peculiar affliction were related to a word or an idea; the simple hearing of the name of an item was able to induce its detailed envisioning in Tesla's mind. Most of his inventions would have been *apriori visualized* in detail in his mind.(*picture thinking*). This perfect photographic memory was perhaps a hereditary inheritance from his mother, possessing, as said, a natural gift in remembering entire epic poems - who knows?

Hungary and France

After moving to Budapest in 1881 he started to work in Tivadar Puskás's Hungarian National Telephone Company. There, he worked with Nebojša Petrović, a young inventor from Austria, on a project using twin turbines to create continual power. On the opening of the telephone exchange in Budapest, 1881, Tesla became the chief electrician of the company, and later, the engineer for the country's first telephone system. He also deviced a telephone repeater or amplifier, but according to others, the first loudspeaker. In 1882 he moved to Paris, attending the *Continental Edison Company*, where he was charged with the designing of improvements for electric equipments. In the same year, Tesla built the induction motor and improved a range of applications using rotating magnetic fields for which he received patents in 1888. After the death of his mother, in April 1882. he fell ill. Recuperation followed in Gospić and Tomingaj, his mother's birthplace.

United States

Tesla arrived in New York on 06.06.1884 with a recommendation letter from Charles Batchelor, his former manager, to Thomas Alva Edison, in which was stipulated textually: "*I know two great men: you are one of them; the other is this young man*". Tesla got the task to redisign Edison company's DC motors

and generators. He claimed later that he was offered US$50,000 (~ US$1.1 million in 2007, adjusted for inflation) for this task. Tesla gave the Edison company several efficient new patents, but as he asked in 1885 about the payment, Edison replied: "Tesla, you don't understand our American humor" and refused to pay. T. resigned after a new refuse of Edison to raise his weekly salary from 18 USD to 25. After a period of digging ditches for the Edison company, T. formed his own company, *Tesla Electric Light & Manufacturing*. The initial investors disagreed with T's plan for alternating current and he was forced again to work as a common worker a year to feed himself and to subventionate his next project. In 1887, he invented the brushless alternating current motor, presented to the AIEE (now IEEE) in 1888. In the same year, he started to develop his Tesla coil and began working with George Westinghouse at Westinghouse Electric & Manufacturing Company. In April of 1887, Tesla began investigating the X-rays, with his own single node vacuum tubes, a device without target electrode. Tesla was aware about the damages of these rays on the skin, but considered that the ozone and the nitrous acide are merely responsible and not the radiation itself. He made photos of his hand bones before Roentgen and sent them later to Roentgen, without commenting his discovery. T. was sure that these waves are longitudinal waves, produced in force-free magnetic fields, like in plasma, a fact confirmed also by others.
. This concept was demonstrated in 1891 (see fig.2). Unfortunately, much of these early researches of T. were lost in the 5th Avenue laboratory fire in March 1895. T.proposed later, in 1904, a "world system" in which energy could be transmitted wireless through various media, starting from a high-power ultraviolet beam forming a vertical ionized channel directly above the transmitter-receiver stations. The same concept was applied in further inventions of T., like the virtual lighting rods, the electrolaser electroshock weapon, being proposed for disabling war vehicles.

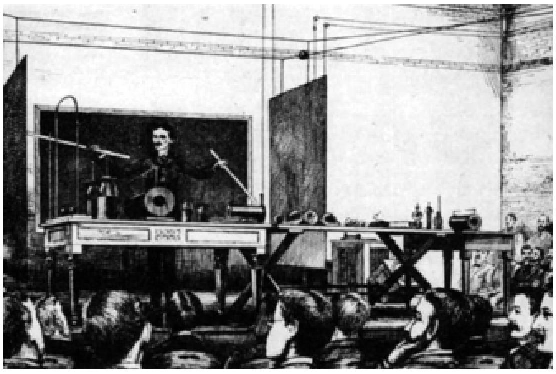

Fig.2. Tesla demonstrating his theory about the wireless transmission of energy waves in 1891[*Courtesy of Wikipedia*]

II. WIRELESS ENERGY TRANSMISSION – THE FIRST 100 YEARS' LANDMARKS [2]

1864 – James Clerk Maxwell – the mathematical model of electromagnetic radiation

1888 – Heinrich Hertz – the *apparatus for generating electromagnetic waves* – by many considered as the first radio transmitter.

1894 – Jagdish Chandra Bose ignited gunpower and rang a bell with electromagnetic waves.

1895 – Jagdish Chandra Bose succeeded to transmit electromagnetic signals at a distance of approx. one mile.

1897 – Nikola Tesla (the real inventor of the radio, inventor of microwaves and alternating current) patented his first inventions in the field of wireless energy transmission using for experiments his Colorado Springs tower.

1900 – Gulielmo Marconi failed to patent his radio invention . The patent office remarks: "*Marconi's pretended ignorance of the nature of a "Tesla oscillator" being little short of absurd...*"

1901 – Gulielmo Marconi sends and receives signals over the Atlantic. Replying to one of his collaborators, engineer Otis Pond, Tesla answers: "*Marconi is a good fellow. Let him continue. He is using **seventeen of my patents**.*"

1904 – at the St. Louis World Fair, a prize was offered for operating an aeromodel having a motor of 0.1 HP from a distance of 100 ft.

1926 – Shintaro Uda and Hidetsugu Yagi published their first article concerning the future Yagi antenna.

1964 – CBS News presented a reality program in which William C. Brown (former technical director of *JPL Raytheon*) and Walter Cronkite demonstrated the operation of a microwave-powered model helicopter, supplied from a microwave beam.

Starting with the 1975 Goldstone Deep Space Communications Experiments a large range of researches, using powerful microwave devices and lasers are now currently performed.

III. TESLA IN COLORADO SPRINGS [1, 2, 4, 5]

About a year before his lecture on wireless energy transmission (1891) T. arrived to the conviction that rarefied air can be a suitable conductor and therefore he went to Colorado Springs to build a transmission station in this part of the Rockies. Leonard E. Curtis, a friend,, found land and provided power for the research from the El Paso Power Company of Colorado Springs and Colonel John Jacob Astor contributed with 30,000 US$ to the construction. Nobody knew exactly what Tesla intended to perform in this laboratory (fig.2) erected on the highest mountain of the Southern Rockies– the Pikes Peak – he generally informed the press that he wants to transmit a signal from the Pikes Peak to Paris.

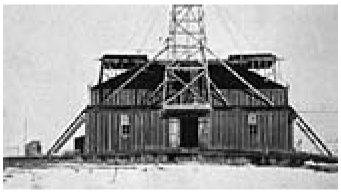

Fig.3. Tesla's Pikes Peak experimental station near Colorado Springs *[Courtesy of PBS]*[

What was experimented in this experimental station is still not clear. In Colorado, with its strong storms, T. performed measurements and soon came to the idea that the earth is a relatively good conductor. He emitted the hypothesis that man could transmit strong impulses to any location on Earth practically without losses. To confirm his theory he constructed a new laboratory in Colorado Springs that would be able to produce the strong impulses that will be conducted to the earth. This new laboratory has a rolled back roof to prevent it from sparks and a wooden tower 80 ft high. On its top was placed a 142 ft metal mast that supported a large copper sphere. Inside the wooden tower was placed a huge Tesla coil. In an experiment of one second, the secondary coil produced wonderful electric sparks and a blue corolla. T. ordered to repeat the experiment without a time limit. Huge 100 ft long man-made lightning bolts were produced from the metal mast to the earth. The play came to an end with the burning of the power plant's generators. Since this event, T. received no more free electricity for his experiments from the El Paso Power Plant. The experiments in Colorado Spring lasted 9 months. Though T. wrote all the experiments in his diary, a question remains still not elucidated: did T. transmit powerful energy waves at Pikes Peak? Some reports conclude that several vacuum tubes planted in the soil in a certain distance from his laboratory were alighted, but this fact can be attributed to the specific high conductivity of this soil [1].

Another approach of T. was on the resonance frequency of the atmosphere between the earth's surface and the ionosphere. T. calculated that this may be about 8 Hz, a result which was verified in the 50's by other researchers that reached the same result.

A third approach of T. was in the field of the ionosphere. T. anticipated correctly that this high stratus of the atmosphere may be highly ionized and therefore highly conductive. He started to think about a device able to transmit electrical energy from the Earth's surface to this high altitude. During this study, he received a repeating signal through his transmitter. He considered – and despite his ridiculization at his time for this announcement - today we may think too that Tesla was perhaps *the first person on Earth receiving a cosmic radio signal.*

IV. THE LECTURES OF TESLA AND HIS PREDICTIONS [1, 2, 4, 5, 6]

Hertz had demonstrated the existence of electromagnetic waves in 1887 using as source of high frequency oscillations the sparks produced by discharges of condensers [6]. In his experiments, Tesla needed high frequency power on a vast scale and at very high voltages. In 1891 Tesla developed an AC generator with 384 poles and an output frequency of 10,000 Hz and soon he invented other generators even at higher frequencies, up to 25,000 Hz. In his study of increasing frequency and voltages, he started with the invention of such giant rotating machines, but finally he came to the conclusion that they are unable to produce the necessary effects and switched to other alternatives. Tesla was all the time convinced that undamped current generation is very important, a method which at his time was still inapplicable and will be introduced only after 1910. His early models utilizing the induction principle with stationary coils formed the equipment used for the large commercial machines built afterwards for radio communications. In his experiments Tesla used tuned circuits, reduction coils and oscillatory spark circuits, which, combined with an oscillation transformer create spectacular arc discharges. He exposed his theory in some famous lectures. The first of them was in 1892, before the American Institute of Electrical Engineers in New York, the second, also in 1892, before the Institution for electrical Engineers and the Royal Institution in London, the Societe Internationale Francaise des Electriciens and the Societe Francaise de Physique in Paris and the third in 1893 before the Franklin Institute in Philadelphia and the National Electric Light Association in St. Louis. In these lectures, Tesla included also references on the structure of matter. In 1893 he also had an extensive exhibit at the Chicago World's Fair. A couple of years before, he explained how metals and dielectric materials could be heated using high frequency coils. He also described the effect of high frequency on the human body (diathermy). He produced vacuum tubes and introduced them in high frequency fields. In this way, he became the father of the neon tube and of the fluorescent lamp. He predicted the use of cheap synchronous electrical clocks. Such clocks were presented at the World's Fair in 1893. Tesla claimed that the future of aviation – than still inexistent, except the balloons - depended on the use of aluminum. Aluminum was a scarce and expensive material at this time and only the development of electricity contributed essentially to its price reduction. Tesla described in his early lectures and patents devices that became important many years later. For example, rotary sparks gaps and series spark gaps with small spacings predicted by T. in 1892-93 became a main issue in the wireless telegraphy from 1909 to 1920. In February 1892, Sir William Crookes published a prediction concerning the possibility of electromagnetic waves to be used for communications. Tesla has the idea to disturb the electrostatic field of the Earth using standing waves by excitation of its entire surface with high frequency power and than taking off power anywhere. Tesla described in his lecture in 1893 large antennas connected to the ground by wires for both purposes – transmission and reception and emphasizes the importance of applying the *electrical resonance principle to these schemes, using even variable tuning*. In 1896 Tesla succeeded to transmit electromagnetic signals to a boat on the Hudson River. About 1900, talking about the radio, he declared: "*I have no doubt that it will prove very efficient in enlightening the masses, particularly in still uncivilized countries and less accessible regions, and that it will add materially to general safety comfort and convenience, and maintenance of peaceful plants, all of which are capable of transmitting individualized signals to the uttermost confines of the earth. Each of them will be preferably located near some important center of civilization and the news that it receives through any channel will be flashed to all points of the globe. A cheap and simple device, which might be carried in one's pocket, may then be set up somewhere on sea or land, and will record the world's news or such special messages as may be intended for it.*" Since 1893, Tesla put as basic objective for himself a worldwide range of grandiose electrical effects, many of his priory invented patents were left for others to make from them less ambitious, but more practical applications. A few other researchers, inspired by his experiments and revelations, like Marconi, used his published patents for their own profit. [1].

V. TESLA – FATHER OF THE AC SYSTEM[1,16]

We remember that as a young scientist Tesla had to compete with the then universally recognized "Father of the DC electricity", Edison. The AC system invented by Tesla was much more effective than the DC system proposed by Edison. The facility to transport electrical energy at long distances was the main reason which determined the abandon of DC networks in favor of Tesla's AC network. The Tesla system was adopted for the first time at the Niagara Falls power plant, which was put in service in 1895. The first recorded assets for economical use of the Niagara Falls waters are dated 1759 (the Daniel Joncairs sawmill's channel). The Niagara Hydraulic Power & Manufacturing Company was founded in 1853. In 1875, the water turbines in the new erected powerhouse began to turn, but electrical power was produced commercially here only starting from 1879, since Schoellkopf introduced electrical technology to his powerhouse turbines. This was the start of one of the first power stations in the world. Illuminating the spectacular falls was a desiderate of many sponsors. In 1860, this occurred using expensive calcium flares, but in 1881, Charles Brush installed electric carbon arc lights, supplied by a small DC generator. In 1904 a new power plant, featuring 34,000 HP was built. In 1918, Schoellkopf's Hydraulic Power Company merged with the Edward Dean Adams' Niagara Falls Power Company. In 1886, Thomas Evershed proposed a project of 200,000 HP electricity generation at Niagara Falls, but this plan was demised due to the impossibility to distribute DC power at long distances. The Niagara Falls Power Company offered a 100,000 US$ award for anyone who could invent a system able to transmit electricity long distance. No one responded to this offer, because nobody was able to oppose to Edison, except Tesla. The greatest scientific minds of the world met in London to discuss the solutions. Against the advice of Thomas Edison and William Kelvin, Tesla's alternating current system was selected as the standard to be utilized. George Westinghouse started to develop Tesla's system. In 1883, Westinghouse replaced the illumination system of the Falls with AC technology. Ten years later, on May 6th, 1893, the Cataract Construction Company, a subsidiary founded in 1889 of the Niagara Falls Power Company, headed by the world's greatest financiers (J.P. Morgan, John Astor, William Vanderbilt and Edward Dean Adams), decided to use in its works in the Niagara Falls region alternating current (AC) for power generation and transmission. A new era in the history of electricity began. The AC system – today extended in the entire world – is one of the major inventions in electroenergetics, and all this - thanks to Tesla.

VI. FROM COLORADO SPRINGS BACK TO NEW YORK [1] .

Back to New York, Tesla wrote an enthousiastic paper for the "Century Magazine", where he describes in a futuristic view means to capture the Sun's radiation energy, to control the weather using electricity, predicts machines that would make wars impossible, and exposes his theory on the worldwide wireless energy transmission, as a global network that would link power stations, telecommunication, radio and even transmit images at remote locations. One of the most powerful magnats of this time, J.P. Morgan, offered to Tesla a capital of 150,000 US$ to build a transmission tower and a power plant, but the sum was too small to cover all the expenses. An offer of 1,000,000 US$ would be more reasonable for this goal. T. accepted this sum and started the construction works. Unfortunately, the history was cruel with this project. After tangled construction phases, due to lack of funds, in 1917 the Marines dynamited it by order of the USA Government, to avoid German spies' use.

VII. TESLA – FATHER OF ROBOTICS [1].

Arrived in New York from Colorado Springs, Tesla tried to shock the assistance in his presentations. For example, a short time after his arrival, in 1898, he presented in the Madison Square Garden arena in New York, in an electrical exhibition, *the world's first radio controlled vessel model.* This is the first attempt to build *automatic robots.* Tesla Patent Nr. 613,809 describes the first device having a wireless remote control. The working model, the *teleautomaton* was controlled with radio signals and powered with an internal battery. On the device were mounted some small lamps by means of which – by switching them wireless on and off from the remote controller, Tesla responded to some easy mathematical questions of the assistance. Being questionned by a reporter about the possibility to use wireless controlled robotics in war missions, like explosive charges' bearing machines, T.replyed: "*You do not see there a wireless torpedo, you see there the first of a race of robots, mechanical men which will do the laborious work of the human race.*"

VIII. TESLA – FATHER OF WIRELESS [1,2,3,5,6]

In a paper entitled "*The True Wireless*"[3], published in the *Electrical Experimenter* in May 1919, Tesla explains his patent concerning wireless transmission of energy using earth's electric resonance in a more popular language: *The arrangement, as I described it in detail, is shown in Fig. 8 [Fig.5 – P.B.]*[3]. *In this case an alternator energizes the primary of a transformer, the high tension secondary of which is connected to the ground and an elevated capacity and tuned to the imprest oscillations. The receiving circuit consists of an inductance connected to the ground and to an elevated terminal without break and is resonantly responsive to the transmitted oscillations.*

Fig. 5. Tesla's System of Wireless Transmission Thru the Earth as Actually Exposed In His Lectures Before the Franklin Institute and Electric Light Association in February and March, 1893 [3]

I gave to the world a wireless system of potentialities far beyond anything before conceived. *I made explicit and repeated statements that I contemplated transmission, absolutely unlimited as to terrestrial distance and amount of energy. But, altho I have overcome all obstacles which seemed in the beginning unsurmountable and found elegant solutions of all the problems which confronted me, yet, even at this very day, the majority of experts are still blind to the possibilities which are within easy attainment. My confidence that a signal could be easily flashed around the globe was strengthened thru the discovery of the "rotating brush," a wonderful phenomenon which I have fully described in my address before the Institution of Electrical Engineers, London, in 1892… This is undoubtedly the most delicate wireless detector known, but for a long time it was hard to produce and to maintain in the sensitive state. These difficulties do not exist now and I am looking to valuable applications of this device, particularly in connection with the high-speed photographic method, which I suggested, in wireless, as well as in wire, transmission"*[3].

IX.NOBEL PRIZE CONTROVERSIES [1].

Thomas Edison and Tesla were proposed as potential laureates to share the Nobel Prize of 1915 in a press dispatch, but finally due to their reciprocal animosity, the prize was not given to them., despite their enormous scientific contributions. In the following events after the rumors, neither Tesla nor

Edison won the prize (although Edison did receive one of 38 possible bids in 1915, and Tesla did receive one bid out of 38 in 1937). Earlier, rumors circulated that Tesla was have been nominated for the Nobel Prize of 1912, for his experiments with tuned circuits using high-voltage high-frequency resonant transformers. In 1915, Tesla filed an unsuccessful lawsuit against Marconi.

X. TESLA'S AWARDS [1].

For his multilateral groundwork in theoretical electrotechnics and for his prodigious inventor's and teacher's activity Tesla was awarded with some of the highest titles and prizes a scientist and an engineer can dream about during his life – except the Nobel Prize, that he virtually might have received instead of Marconi if in 1909 the Nobel Commission would had been correct. Tesla received the Elliott Cresson Gold Medal in 1893, the Edison Medal in 1916 and the John Scott Medal in 1934.

XI. THE RIVAL APPEARS [10, 12, 13, 14, 15]

Fig.6. Guglielmo Marconi, [*Courtesy of INVENTORS*] [10]

Guglielmo Marconi (fig.6) was born on April 25,.1874 in Bologna, Italy. His father was a rich Italian landowner and his mother, a granddaughter of the founder of the Jameson whiskey distillery. Marconi learned in Bologna in the lab of Augusto Righi, in Florence at the Istituto Cavallero, and, finally in Livorno. First experiments were performed at home, in December 1894 . After sending LW signals at a distance of 1 mile in 1895, he went to England and founded the Marconi Company at Chelmsford, Essex in 1897. His first patent in wireless telegraphy, Nr. 12039, was received on June 2, 1896, followed in July by experiments from the General Post Office building in London in a distance of 1.5 miles. On September 2, 1896 the span had increased to 8 miles with tests at Salisbury plain and then, on 11.05.1897, across the Bristol Channel (3.5 miles). Daily Express, in July 1898 was the first newspaper using radiotelegraph. Another device was installed at the board of Queen Victoria's Royal yacht. The extension of the new invention was really rapid. In December 1898 wireless telegraphy was installed between East Goodwin light ship and the South Foreland lighthouse and on March 3, 1899, wireless communication was employed to save life. In summer 1899 the Marconi's wireless signals crossed the English Channel and on November 15, 1899 the first ocean wireless transmissions linked ships. On April 26, 1900, M. received his patent Nr. 7777 for *"Tuned Syntonic Telegraphy"*, an invention that used tuned circuits, enabling a wireless set to be tuned to specific emitting station (like a radio receiver today). On January 23, 1901 the first long distance (196 miles) wireless transmission was performed from the Isle of Wight to The Lizzard in Cornwall. The next task was to transmit over the Atlantic and this was realized on Thursday the 12th of December 1901.The letter "S" transmitted from Poldhu, Cornwall, was – according to Marconi and his assistant, Georges Piget - received at Signal Hill, St. Johns, Newfoundland. In a span of a few decades, radio transmissions changed the world and brought nations closer to each other. In 1909, Marconi shared the Nobel Prize with Karl Ferdinand Braun, from which he "borrowed" some parts of his work (like Braun's British patent on tuning), as he will recognize later. Guglielmo Marconi used also the patents of others, as we will see in the next chapter.. Marconi's 1901 tests were contested by scientists (Edison and others), motivating that M.receives only parasite signals from the atmosphere. Dr. Jack Belrose estimated that the Poldhu transmitter has a frequency of 850 Hz and what Marconi received were only SW, emitted by the ionosphere. Fearing to be challenged by concurrents, M. conducted new tests over the ocean, this time using a ship. These tests gave coherer-tape reception up to 2,496 km (1,551 mi), and audio reception up to 3,378 km (2,099 mi) during the night and half of these results during daytime, i.e. that Marconi's mid-day Atlantic wireless first crossing in 1901 with LW and MW was seemingly not real. An 1902 unsuccessful test from Glacier Bay confirmed this supposition. In 1903, President Theodore Roosevelt greeted wireless King Edward VII to HM birthday [I still must look for the way - directly or by intermediary ship-stations (?)]. The two Marconi's company radio operators on the "Titanic" rescued survivors by their SOS signals.. In 1915 the Chelmsford Marconi factory, using a vacuum tube transmitter, organized the first entertainment radio broadcast and in 1922 such transmissions became regular (from the Marconi Research Centre at Writtle). Marconi. reached the Italian Senate in 1914 and was made a marchese in 1924 by King Victor Emmanuel III. In 1923 he had adhered to the fascist party of Benito Mussolini, which made him in 1930 President of the Accademia d'Italia. Later he was appointed a Member of the Fascist Grand Council. Marconi died in Rome in 1937 at the age of 63, after a series of heart attacks. All the radio stations in the world kept silence for two minutes. After state funerals his remains were deposed in his house, Villa Griffone, Sasso Marconi, Emilia-Romagna.

XI. A LATE RECOGNITION[2, 9, 12, 13, 17]

Marconi's work is based on copies of patents of many other inventors without their permission. His so-called original "two-circuit" device, a spark-gap transmitter plus a coherer-receiver, was similar to those used by Oliver Lodge in a series of worldwide reported tests in 1894. Tesla disputed that Marconi was able to signal for greater distances than anyone else when using the spark-gap and coherer combination. In 1900 Alexander Stepanovich Popov declared to the Congress of Russian Electrical Engineers: "[...] *the emission and reception of signals by Marconi by means of electric oscillations* [was] *nothing new. In America, the famous engineer Nikola Tesla carried the same experiments in 1893*." The Fascist regime in Italy credited Marconi as inventor of the radio. The doubt is if his own contribution was sufficient to constitute an independent patent, or if his component devices were too similar to the original ones (if not copies) developed years before by Hertz, Popov, Branly, Tesla, and Lodge – and in this case, they are copies. Marconi's "four-circuit" design, having two tuned-circuits at the transmitting and receiver antennas, **British Patent Nr.7777** from 26 April 1900 is a compound of the earlier work of Tesla and other inventors. 5of 9 judges of the Supreme Court stated that Marconi's work had been anticipated by **John Stone Stone** (patent No.714,756) and **Oliver Lodge** (patent No. 609,154). The Supreme Court also studied **Tesla's patent No. 645,576** and noted that **Tesla had used four tuned circuits before Marconi**. In order to defend himself, in 1911 Marconi purchased through his company the Lodge-Muirhead Syndicate, whose main performance was Oliver Lodge's tuning patent, invented in 1897. Thus, the 7777 Patent was vividly discussed at this time from validation to complete rejection. In 1943, the US Supreme Court stated that: "*The Tesla patent No. 645,576, applied for September 2, 1897 and allowed March 20, 1900, disclosed a four-circuit system, having two circuits each at transmitter and receiver, and recommended that all four circuits be tuned to the same frequency. [... He] recognized that his apparatus could, without change, be used for wireless communication, which is dependent upon the transmission of electrical energy.*" In its decision, the court noted: "*Marconi's reputation as the man who first achieved successful radio transmission rests on his original patent, which became reissue No. 11,913, and which is not here [320 U.S. 1, 38] in question. That reputation, however well-deserved, does not entitle him to a patent for every later improvement which he claims in the radio field. Patent cases, like others, must be decided not by weighing the reputations of the litigants, but by careful study of the merits of their respective contentions and proofs*". The court also stated that: "*It is well established that as between two inventors priority of invention will be awarded to the one who by satisfying proof can show that he first conceived of the invention.*" Following to this decision, most of Marconi's patents were overturned by the US Supreme Court. A decision that came unfortunately 9 months after Tesla's death.and

which was pronounced not mainly in order to do simply justice. At the time, the US Army and Marconi's company were involved in a trial on the radio patent rights, and in order to anullate Tesla's former claims for compensation, the Court nullified Marconi's other inventions. The priority of Tesla's US Patent No.645, 576 on the Marconi's US Patent No.763,772 is more evident if we use the following suggestive comparative timeline diagram, published in the Internet (Fig.9) [1]

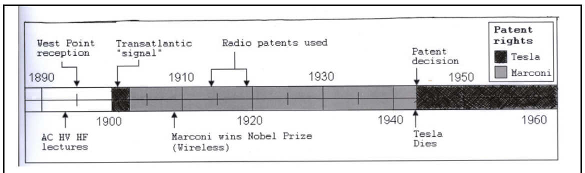

Fig. 9. Comparative timeline diagram illustrating the priority of Tesla's Patent No.645,576 on Marconi's radio patent [*Courtesy of Wikipedia*][1]

Tesla was not alone in claiming against Marconi. Oliver Lodge claimed the usage of his unpatented ideas in Marconi's first radio patent. Don Kimberlin comments: *"…What did happen by April 1900 was that Marconi uniquely had combined Professor Righi's transmitter, Branly's coherer, Tesla's elevated antenna and Lodge's tuned circuits to realize what ultimately became first wireless telegraphy…"*[18]. In order to compare the patents, please see the figures (Fig.5, 7, 8a and b). From these drawings results that the use of resonant circuits was clearly primordially demonstrated (1893) and filed (1898) by Tesla, the Marconi patent was only afterwards "adjusted". Marconi's invention is only an application of Tesla's (and of others') prior researches and studies. The differences consist in the used media – in Tesla's patent it was the Earth, in Marconi's patent it is the air. In Tesla's patent, a high frequency polyphasic alternator provides the HF initial impulses, whereas in Marconi's feature, the impulses are produced by switching on-off manually the telegraph's switch. The differences are not in the principle, but in the application's purpose. Tesla – as discussed – wanted to create his planned worldwide wireless system, whereas Marconi – using the wireless transmission knowledge and technology previously set by Tesla and others – performed an apparatus for common use– the radiotelegraph - and fructified the results.

XII. CONCLUSION

Tesla was the first to invent the radio. Marconi did not really invent the radio, he only combined, copied and adapted patents of Tesla and others and commercialized them as his own patent. He died in a plenty of glory and richess, whereas Tesla died as a poor man. No comments…

RF Harvesting – Experiment 1 (PASS)

by w5fcx | Feb 24, 2017 | Antennas, electronics, Software-defined Antenna | 0 comments

I'm happy to report that the first experiment on RF harvesting for DC power for the BatBeam project was a big success. I recorded the event, with the help of my wife Sandy, who did an excellent job taking the video, which you will find below. The significance of this experiment may not be apparent at first. What it means is that the first step in establishing the feasibility of a fully-wireless J-Box has been taken successfully. This is a critical step to have passed, as we must have DC power at each J-Box in order to power the RF switching relay and J-Box controller circuitry.

Here's the video. The schematic of the simple circuit along with some additional photos are below.

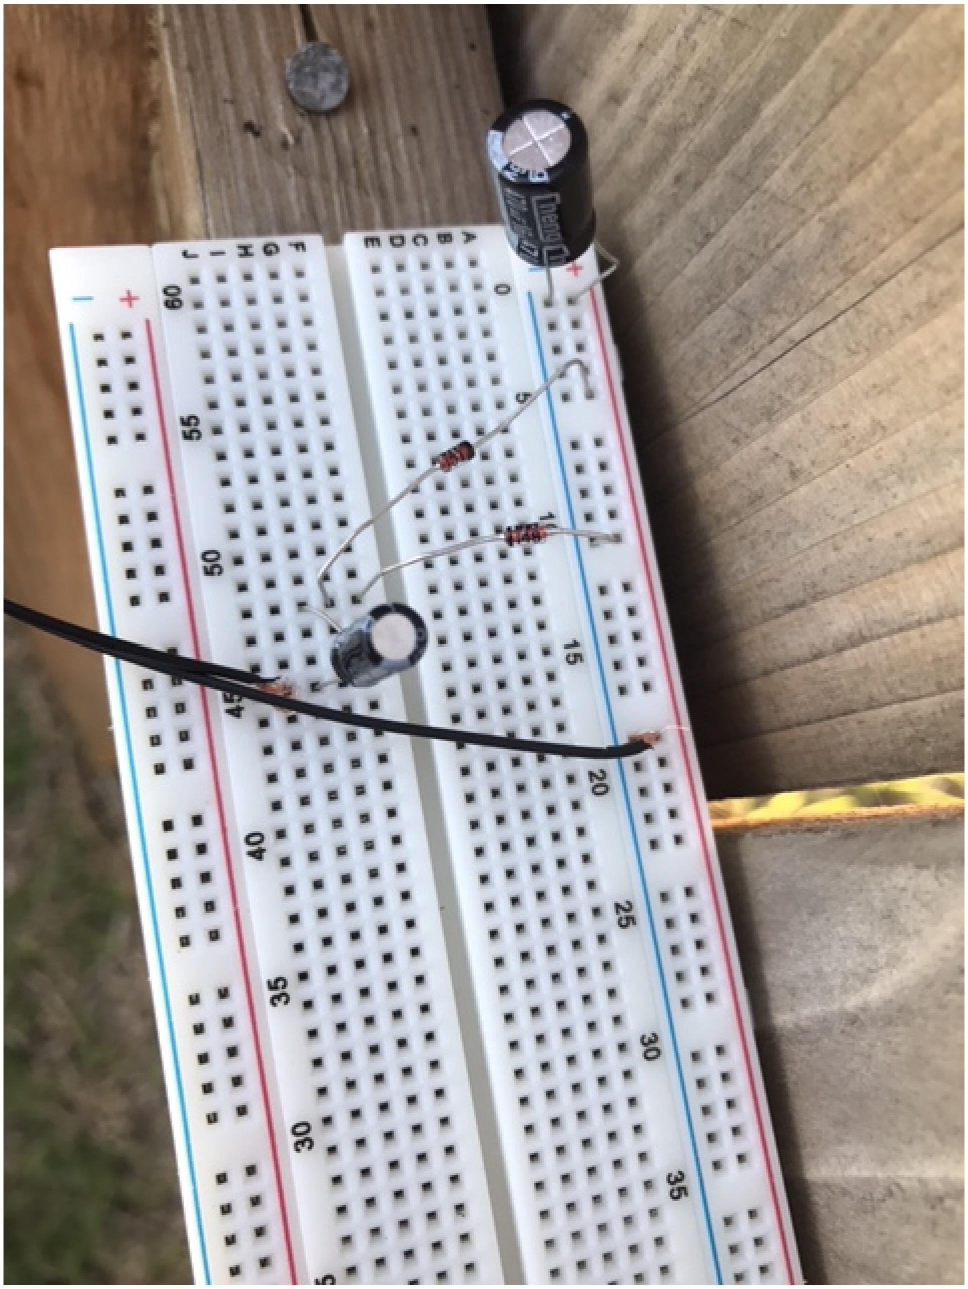
In the above schematic, the signal generator is replaced by the RF harvesting inductor, 10 turns of wire wrapped about the end of one G5RV antenna segment (a 20 meter G5RV). The RF harvesting inductor is shown below.

Below you will see the extremely simple proof of concept rectifier circuit, along with the RF inductor feedline.



This concludes RF harvest experiment 1, which PASSED.

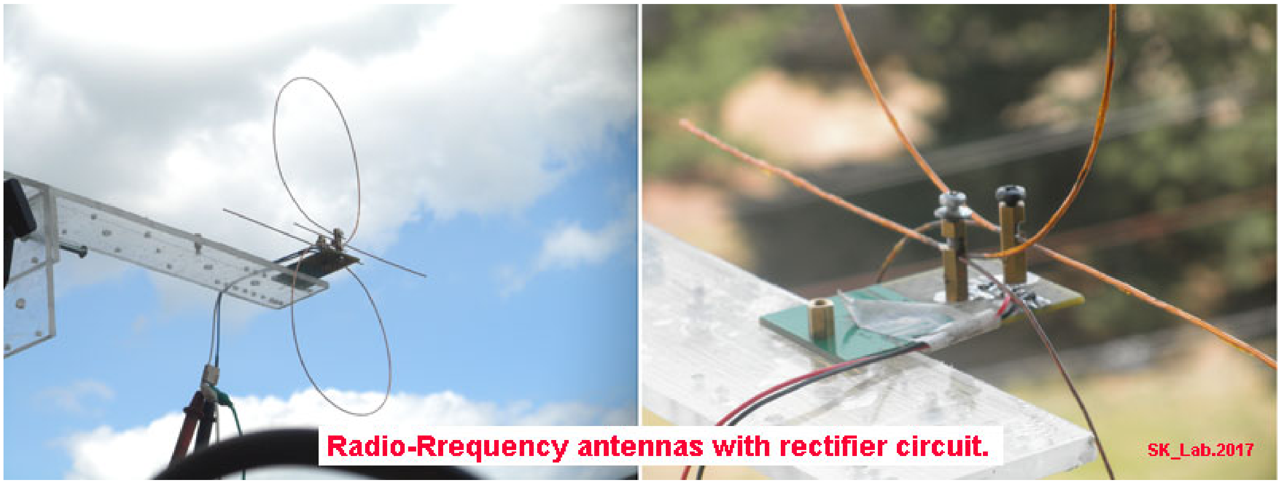
Extraction of energy from radio waves.

Simply, I like to check things.

Harvesting power from radio waves.

Assuming that most people came here to just find out how much energy can be obtained from radio waves, we will be short.

On the banner, two '**D**ual-**Loop**' directional antennas, designed specifically to collect power at 750MHz. One is connected to 100uA (700Ohms) head, and the average current you can see on it. Both antennas have 'on-board' rectifiers.



Radio-Rrequency antennas with rectifier circuit.
SK_Lab.2017

Reality is not as good as we would like. One antenna produces about 1 volt (at 10MOhms), and a current of about 0,4 mA (at 700Ohms).

The circuit is simple as a crystal receiver. Diodes with capacitors work as a voltage doubler (rectifier). The remaining inductors and capacitors isolate the output from high frequency.

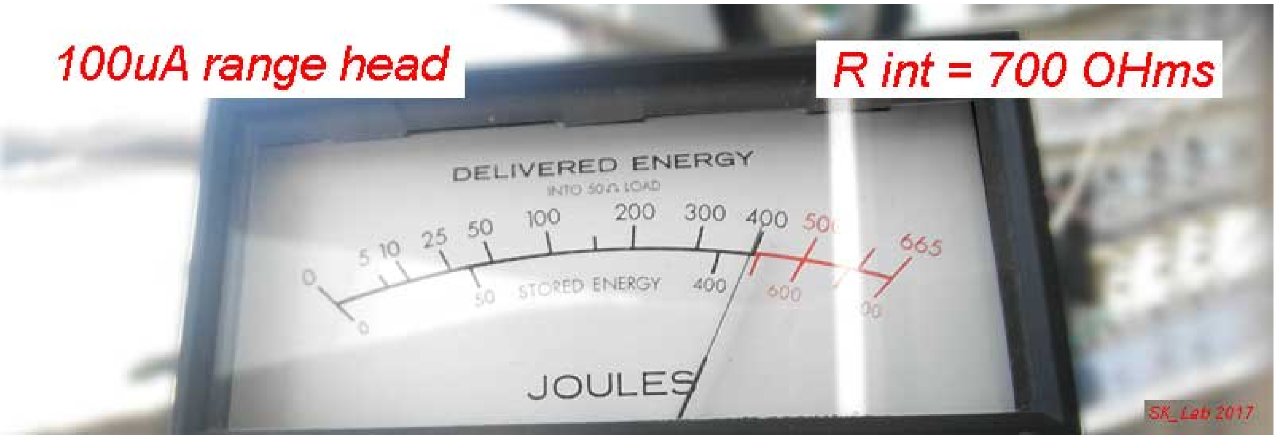
* The output voltage and current may vary, depending on the conditions.

Harvesting RF power. Absorbs energy from cell towers at 750MHz.

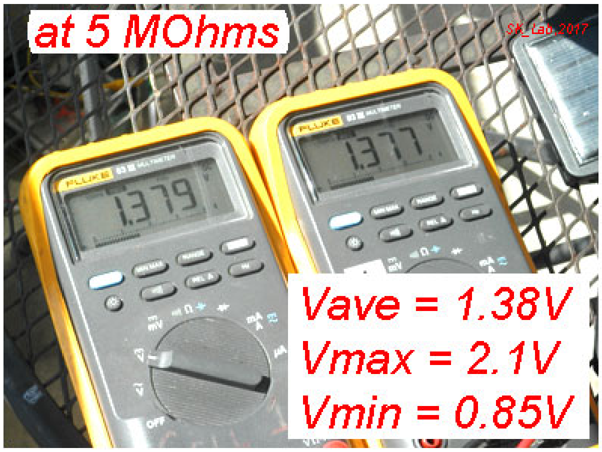
Any RF diodes with junction capacitance less then 1.5pF will be suitable for this application. See the end of this page for a suitable choice.

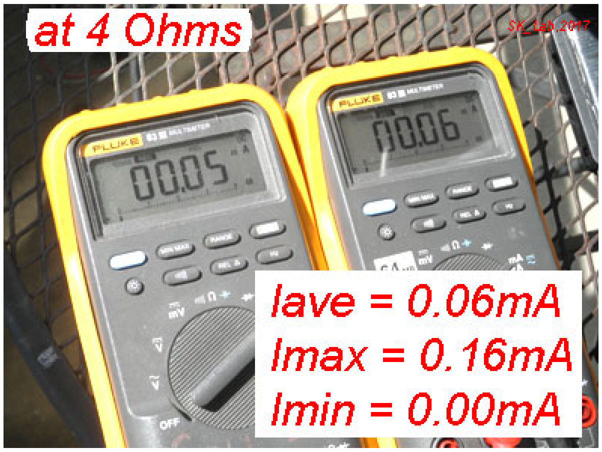
It's hard to believe, but the old style panel meter is the best indicator of the power that was obtained.



After simple calculations, the total power, received at the moment, is about 0.5mW.

It was a good, top result. But interesting to know what average power can be expected. A simple installation allows me to get more reliable results. We measure the open voltage (at 5 MOhms) and short current (at 4 Ohms) produced by one antenna. The measurement time for obtaining the average is about half an hour. Both multimeters work together to eliminate an accidental error.





And here we return to reality. During the measurement time, the average power taken from the air by one antenna was ~0.02mW. Even the fact that the maximum power jumped to ~0.8 mW did not change anything.

For most people, these digits do not say anything. So let's move on to the practical side.

Suppose you want to light the LED. 0.02mW is not enough to light the LED even very, very dimly. One way to do this is to charge the capacitor and when enough energy is stored, discharge it through the LED.

Let's say you want to light a white LED (3V), with a current of 0.01A, for 0.1 second. It requires 3**V***0.01**A***0.1**sec**.= 0.003**J**oule. The antenna produces, an average, 0.00002W*1**sec**.=0.00002**J** each second. This means that to get the necessary energy (0.003J), you need to wait 150 seconds or 2.5 minutes.

But it is not all that bad. During the 24 hours, this simple setup with one antenna, can collect about 1.7**J** of totally free energy. This is enough that a data logger would work, and once a day transmit data via wireless or so. For example, a device (or LED) consuming 10mA at 3.6V can run at least 45 seconds per day on the stored energy.

In order to make this idea run, in your particular case, you need to:
a) find a 'hot spot' using any RF detector;
b) with any SDR Receiver find RF frequency with max. power;
c) make a simple antenna (Dual-Loop or so), add RF rectifier and enjoy 'free' energy :)

Yes. It's all. It's simple like that.

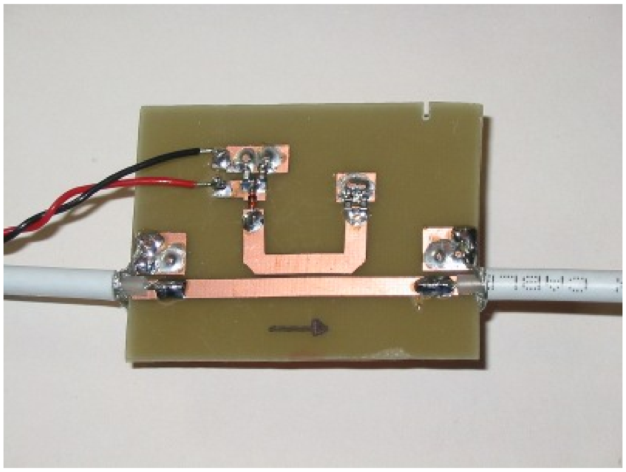
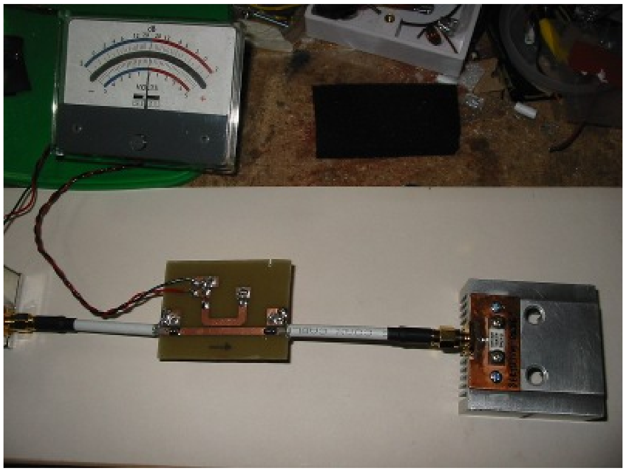
Microwave directional coupler - and an RF detector

More deviations from the main project.

I was concerned that, as I manage to generate a bit more power (hopefully!) at microwave frequencies, a simple RF probe would not be sufficient for power measurement, and the diode could be over-voltaged. A directional coupler allows a small amound of the forward signal to be sampled and measured. A very simple design is to use microstrip, as shown in the photo. A BAT85 Schottky diode is used as the detector, with 100pF and 10nF decoupling. The other end of the coupling loop is terminated with two 100 ohm resistors in parallel.

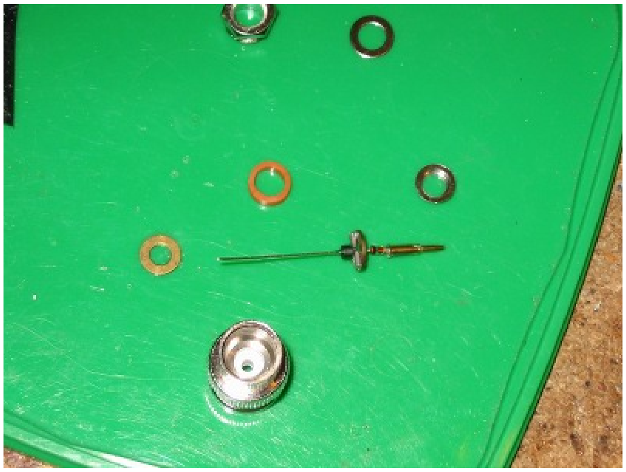


Here it is in use, with the signal being dissipated in the dummy load. A 100 microamp meter is used as the detector (100-0-100 microamps here since that's what I had available). It seems to work well, and is very directional indeed - very little signal is measured if it's connected the other way round. I don't know what the coupling is with any accuracy yet, but it will be fine for relative measurements for now.



Having proved its success, I will probably make one with forward and reverse detectors that can be put in a box and used as a "through line" power meter for forward and reverse measurements.

I also wanted something a bit more reliable than my hand held RF probe for making measurements of power in test rigs. With that, since it really needs to be mounted in a screened tube, the signal can vary a bit depending on how the probe is set up. I thought that if I could put the RF detector into a BNC plug, then I might get rather more consistent measurements. Here are the components before assembly into a BNC compression plug. The BAT85 diode fits right down near the probe; two SMD 1nF capacitors are soldered to a brass washer, and to the other end of the diode, to give the decoupling; and for good measure, the output is taken through a 2mm ferrite bead. When I get round to scanning some circuit diagrams I'll try to remember to add a sketch of the arrangement here.



This new detector seems to be much more consistent than the RF probe, though I'm not yet happy that I can be sure of power measurements calculated from the detected DC voltage!

The Basics of Patch Antennas, Updated

By D. Orban and G.J.K. Moernaut,
Orban Microwave Products
www.orbanmicrowave.com

Introduction

This article introduces the basic concepts of patch antennas. We use a simple rectangular, half wave long, probe-fed patch operating in its fundamental mode as an example.

Topics include principles of operation, impedance matching, radiation patterns, circular polarization, bandwidth, efficiency, alternative feed types, stacked patches and higher mode behavior.

This article was originally published in September 2005. After it was published, we received substantial feedback from those who read it. The article has been revised based upon the feedback we received.

Properties Of A Basic Microstrip Patch

A microstrip or patch antenna is a low-profile antenna that has a number of advantages over other antennas: it is lightweight, inexpensive, and electronics like LNA's and SSPA's can be integrated with these antennas quite easily. While the antenna can be a 3-D structure (wrapped around a cylinder, for example), it is usually flat and that is why patch antennas are sometimes referred to as planar antennas.

Figure 1 shows a patch antenna in its basic form: a flat plate over a ground plane. This antenna is often built of printed circuit board material and the substrate makes up the patch antenna's dielectric. The distance between the patch and the ground plane – the substrate or dielectric height h – determines the bandwidth.

A thicker substrate increases the gain to some extent, but may lead to undesired effects like surface wave excitation: surface waves decrease efficiency and perturb the radiation pattern.

The ground plane should extend beyond the edges of the patch by at least 2 to 3 times the board thickness for proper operation. A ground plane that is too small will result in a reduced front to back ratio.

Making the ground plane larger also increases the gain, but as the ground plane size increases, diffraction near the edges plays less of a role and increasing the size of an already "large" ground plane has very little effect on gain.

In the antenna in *Figure 1*, the center conductor of a coaxial line serves as the feed probe to couple electromagnetic energy in and/or out of the patch. A thicker substrate leads to a longer feed probe, a larger feed probe inductance and a degradation of impedance matching. This can be compensated by using a different feed type and we'll look at alternative feed methods further down.

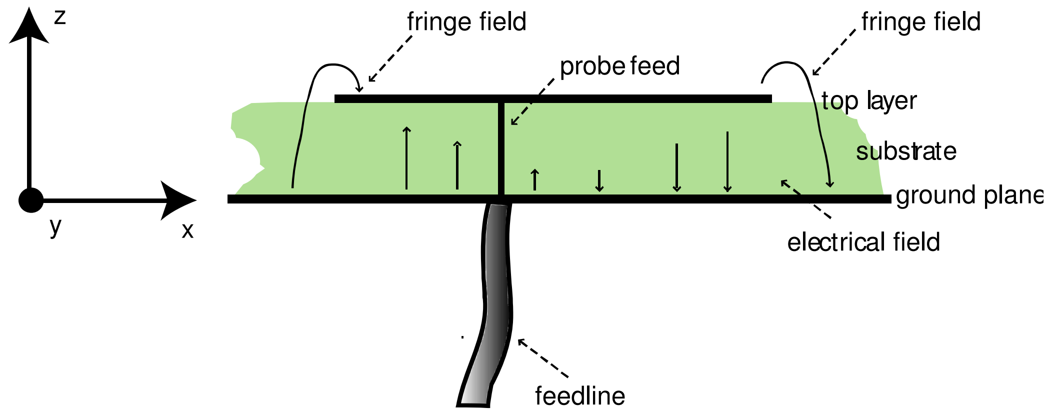

Figure 1: *Cross section of a patch antenna in its basic form*

A half wave long patch operates in what we call the fundamental mode: the electric field is zero at the center of the patch, maximum (positive) on one side, and minimum (negative) on the opposite side. These minima and maxima continuously change side like the phase of the RF signal.

The electric field does not stop abruptly near the patch's edges like it would in a cavity: the field extends beyond the outer periphery. These field extensions are known as fringing fields and cause the patch to radiate. Some popular analytic modeling techniques for patch antennas are based on this leaky-cavity concept and the fundamental mode of a rectangular patch is often denoted using cavity theory like the TM10 mode.

This TM notation often leads to confusion and here is an attempt to explain that: *Figure 1* uses a Cartesian coordinate system, where the x and y axes are parallel with the ground-plane and the z-axis is perpendicular to it.

TM stands for a magnetic field distribution –between patch and ground– that is transverse to the z-axis of the antenna shown in *Figure 1*. This 'transverse' with respect to the z-axis is usually dropped because the magnetic fields in patch antennas are always transverse to their z-axis.

So, we can simplify things and only consider three field components instead of six (magnetic and electric fields in each x, y and z axis): the electric field in the z direction, and the magnetic field components in x and y directions.

In general, modes are designated as TMnmp. The 'p' value is mostly omitted because the electric field variation is considered negligible in the z-axis since only a phase variation exists in the z axis. So, TMnm represents the field variations in the x and y directions. The field variation in the y direction (impedance width direction) is negligible and m is 0. The field has one minimum-to-maximum variation in the x direction (resonance length direction and a half wave long), n is 1 in this case and we say that this patch operates in the TM10 mode.

Dimensions

The resonant length (the x axis in *Figure 2*) determines the resonant frequency and is about $\lambda_d/2$ for a rectangular patch excited in its fundamental mode where λ_d is the wavelength in the PCB material. The patch is actually a bit larger electrically than its physical dimensions due to the fringing fields and the difference between electrical and physical size is mainly dependent on the PC board thickness and dielectric constant of the substrate.

A good approximation for the resonant length is:

$$L \approx 0.49\ \lambda_d = 0.49\ \frac{\lambda_0}{\sqrt{\varepsilon_r}}.$$

This formula includes a first order correction for the edge extension due to the fringing fields, with:

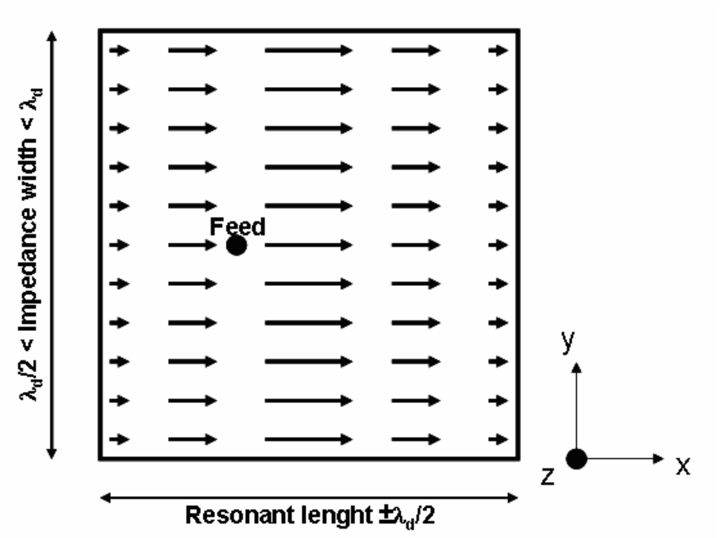
- L = resonant length
- λ_d = wavelength in PC board
- λ_0 = wavelength in free space
- ε_r = dielectric constant of the printed circuit board material

Other parameters that have less influence on the resonant frequency include:

- Ground plane size
- Metal (copper) and dielectric thickness
- Patch (impedance) width

Impedance Matching

The feed position of a patch antenna excited in its fundamental mode is typically located in the center of the patch width direction (y axis) and somewhere along the patch resonant length direction (x axis). The exact position along the resonant length is determined by the electromagnetic field distribution in the patch. Looking at the current (magnetic field) and voltage (electric field) variation along the patch, the current has a *maximum* at the center and a *minimum* near the left and right edges, while the electric field is *zero* in the center and *maximum* near the left and *minimum* near the right edges. Keep in mind that the field distribution constantly changes in amplitude and sign. *Figures 2 and 3* below clarify this:



$\lambda_d/2$ < Impedance width < λ_d
Feed
y
z
x
Resonant lenght $\pm\lambda_d/2$

Figure 2: *Current distribution on the patch surface*

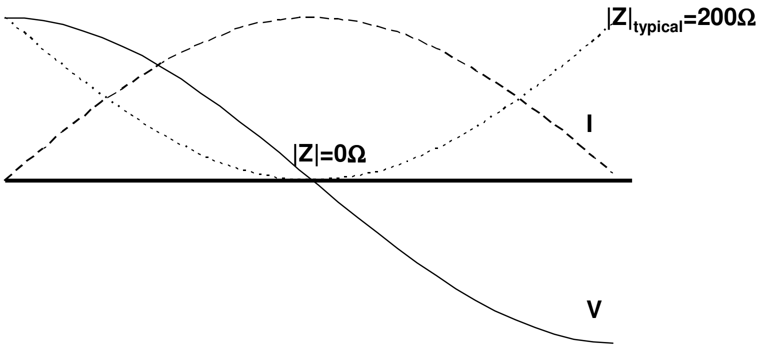


Figure 3: *Voltage (V), current (I) and impedance (|Z|) distribution along the patch's resonant length*

From the magnitude of the current and the voltage, we can determine that the impedance is minimum (theoretically zero Ω) in the center of the patch and maximum (typically a couple hundred Ω) near the edges. This means that there are two points where the impedance is 50 Ω somewhere along the resonant length (x) axis of the element and this is where you would typically connect to the antenna.

The possibility to connect to the patch at other impedance points is quite useful and impedances up to 200 Ω are common. For example, a two element array can be fed with a simple parallel feed by matching the individual patch elements to 100 Ω and connecting them in parallel results in 50 Ω end impedance without the need for impedance transformers. The same woks for a 4 element array with the elements connected at their 200 Ω point.

If you wanted to connect to the edge of the patch and were looking for a specific impedance, you could modify the width of the patch to yield the impedance your are looking for. Increasing the width decreases the impedance.

Fundamental Specifications Of Patch Antennas

Radiation Pattern

A patch antenna radiates power in certain directions and we say that the antenna has directivity (usually expressed in dBi). If the antenna had a 100% radiation efficiency, all directivity would be converted to gain. Typical half wave patches have efficiencies well above 90%.

The directivity of a patch can be estimated quite easily:

The radiating edges of a patch can be seen as two radiating slots placed above a ground-plane and, assuming all radiation occurs in one half of the hemisphere (on the patch side of the ground), we get a 3 dB directivity increase. This would be an antenna with a perfect front-to-back ratio where all radiation occurs towards the front and no radiation towards the back. This front-to-back ratio is highly dependent on ground-plane size and shape in real life.

Another 3 dB can be added because there are 2 slots. The length of these slots typically equals the impedance width (length in the y-axis) of the patch and the width of these slots equals the substrate height. These slots typically have a directivity of 2 to 3 dB compared to an isotropic radiator and behave like a dipole.

All of this results in a total maximum directivity of 8 to 9 dBi.

The rectangular patch excited in its fundamental mode has a maximum directivity in the direction perpendicular to the patch (z-axis or broadside). The directivity decreases when moving away from broadside towards lower elevations. The 3 dB beamwidth is the width at which the gain of the beam decreases by 3 dB relative to the gain in broadside to either side of the main beam.

Figure 4 shows a typical radiation pattern for a square, half wave patch.

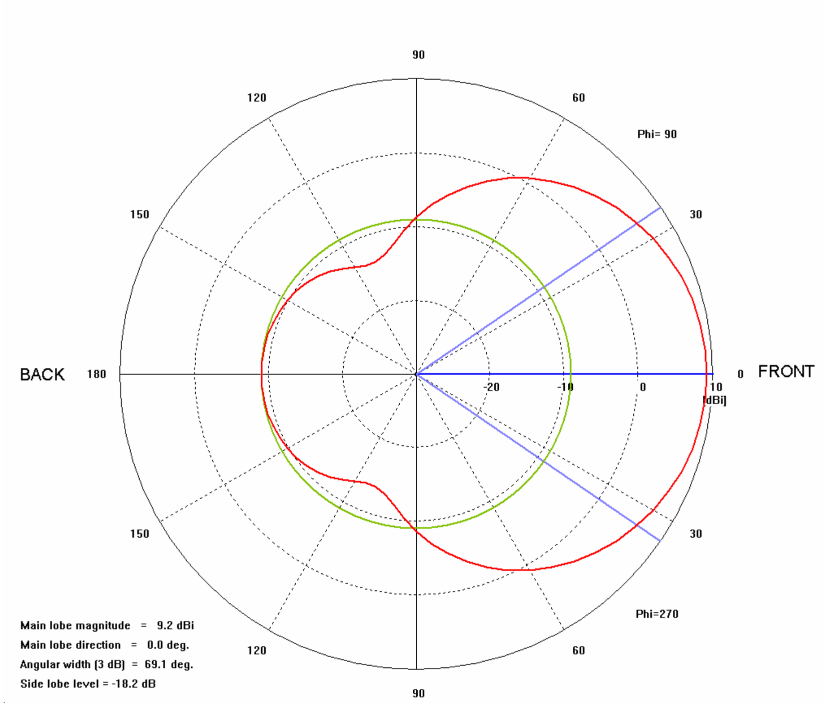

Figure 4: *Typical radiation pattern of a simple square patch*

So far, the directivity has been defined relative to an isotropic radiator and we use dB*i*. An isotropic radiator emits an equal amount of power in all directions and it has no directivity. Antenna directivity can also be specified relative to that of a dipole. A dipole has 2.15 dB*i* of directivity over an isotropic radiator. When we specify the directivity of an antenna relative to a dipole, we use dB*d*.

No antenna losses have been included so far and the integrated average of the directivity pattern over an entire sphere has to be 0 dBi. This implies that creating directivity in a certain direction reduces directivity in other directions.

Antenna Gain

Antennas do not have gain because they are passive structures. Antenna gain is defined as antenna directivity times a factor representing the radiation efficiency. Radiation efficiency is always lower than 100% so the antenna gain is always lower than antenna directivity. This efficiency quantifies the losses in the antenna and is defined as the ratio of radiated power (Pr) to input power (Pi). The input power is transformed into radiated power, surface wave power and a small portion is dissipated due to conductor and dielectric losses. Surface waves are guided waves captured within the substrate and partially radiated and reflected back at the substrate edges. Surface waves are more easily excited when materials with higher dielectric constants and/or thicker materials are used. Surface waves are not excited when air dielectric is used. Several techniques to prevent surface wave excitation exist, but this is beyond the scope of this article.

Antenna gain can also be specified using the total efficiency rather than just the radiation efficiency. This total efficiency is a combination of the radiation efficiency and efficiency linked to the impedance matching of the antenna.

Polarization

The plane in which the electric field varies is also known as the polarization plane. The basic patch covered so far is linearly polarized since the electric field varies in only one direction. This polarization can be anything between vertical and horizontal depending on the orientation of the patch. The polarization plane is the xz-plane in *Figure 1*. For optimum system performance, transmit and receive antennas must have the same polarization. The patch described above yields horizontal polarization and when rotated by 90°, the current flows in the vertical plane and the antenna is now vertically polarized.

A large number of applications like satellite communications, do not work well with linear polarization because the relative orientation of the antennas is unknown and because of Faraday rotation. In these applications, circular polarization is useful since it is not sensitive to antenna orientation. In a circularly polarized antenna, the electric field varies in two orthogonal planes (x and y direction) with the same magnitude and a 90° phase difference. The result is the simultaneous excitation of two modes, i.e. the TM10 mode (x direction) and the TM01 mode (y direction). One of the modes is excited with a 90° phase delay with respect to the other mode. A circularly polarized antenna can either be right-hand circular polarized (RHCP) or left-hand circular polarized (LHCP). The antenna is RHCP when the phases are 0° and -90° for the antenna in *Figure 5* when it radiates towards the reader, and it is LHCP when the phases are 0° and +90°.

To excite circular polarization in a patch we need to do three things:

- Split the signal in two equal parts.
- Feed one signal to the horizontal radiator (x axis) and the other to the vertical radiator (y axis). Each radiator behaves like a pair of radiating slots in the patch antenna as shown in *Figure 5*.
- Change the phase of one of the signals by 90°.

Splitting the signal in half can be done with a Wilkinson power divider or other splitter. If a square patch is fed with two feed points like in *Figure 5* and a 90° delay is added to one of the signal lines, a circularly polarized antenna is built.

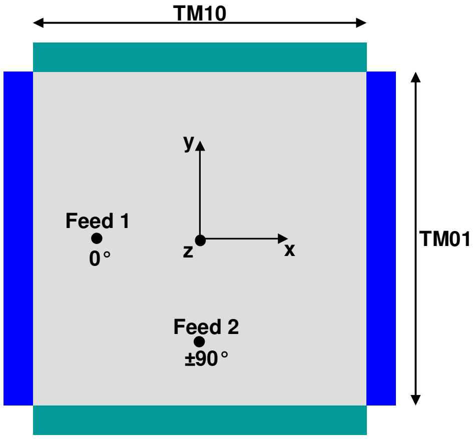

Figure 5: *The nearly square mechanism for circular polarization*

While this works well, the splitter and delay line take up valuable board space, introduce losses, tend to radiate and may degrade the radiation pattern.

A different approach is based on the fact that each patch mode (TM10, TM01) behaves like a parallel RLC resonant circuit. If we make the x and y dimensions of the patch slightly different, there will be two resonant frequencies, fa and fb and we will see two different RLC circuits. This creates a phase shift change versus frequency as shown in *Figure 6*:

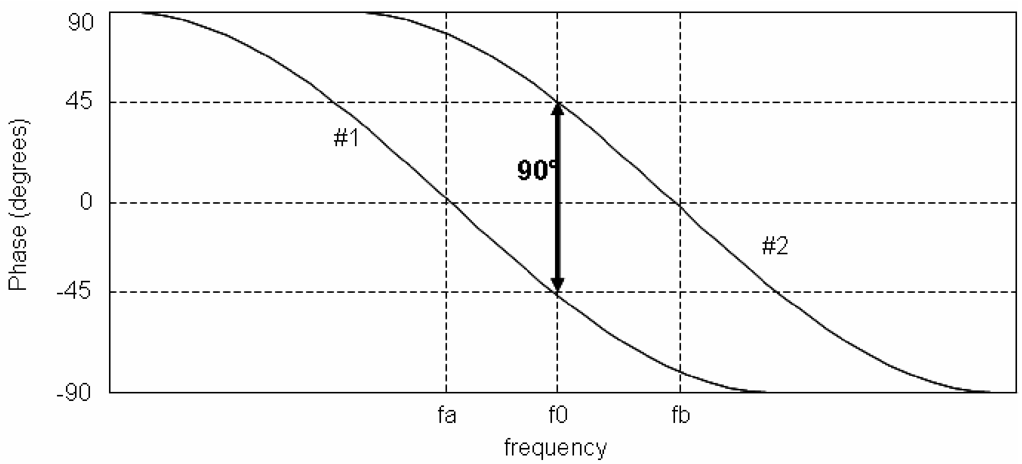

Figure 6: *The dual resonant circuit analogy of the nearly square mechanism*

If we pick these two resonance frequencies right, there will be a small frequency band where the phase difference between the two RLC circuits is 90°.

So, circular polarization can be achieved by building a patch with two resonance frequencies in the orthogonal directions and using the antenna right in between the two resonances at f0. The two modes must be excited with equal power and with a 90° phase difference.

One way to implement this is shown in *Figure 7*: this nearly square patch has slightly different lengths in the x and y axis. This causes the excitation of two orthogonal modes with the required 90° phase shift. Feeding the antenna close to the diagonal splits the power equally between the two orthogonal modes and all three requirements to generate circular polarization have been met.

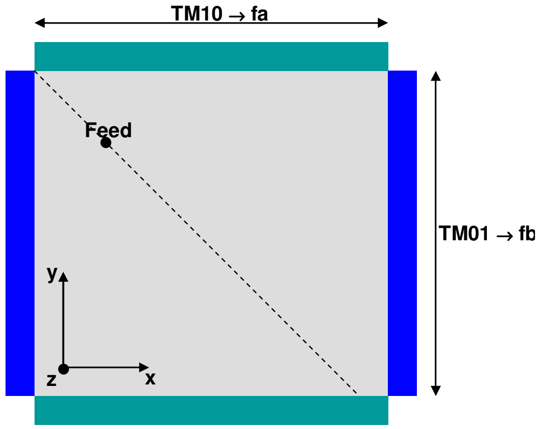

Figure 7: *Nearly square patch fed on the diagonal*

The corners truncated patch (often used in GPS L1 antennas), is another implementation of the same idea. This is shown in *Figure 8*.

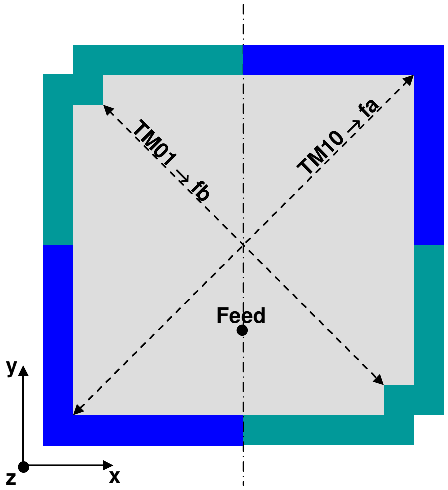

Figure 8: *The corners truncated patch antenna*

The nearly square and corners truncated patches have a smaller (1 to 3%) circular polarization bandwidth than the double fed patch (at least 3%): the polarization bandwidth of the antenna is mainly determined by the bandwidth of the splitter-phase shifter.

The quality of the circular polarization is commonly quantified as the axial ratio (AR) and is expressed in dB. A 3 dB axial ratio is considered sufficient for most applications. Since the phase difference between modes varies with frequency, it is clear that the axial ratio also varies with frequency: it has a theoretical optimum of 0 dB right in between the resonance frequencies of the two orthogonal modes. Not shown so far is that the axial ratio varies with elevation as well: the AR is optimal in broadside (z-axis), degrades towards lower elevations (the x-y plane) and the amount of degradation is highly dependent on the antenna geometry.

The quality of the circular polarization can also be expressed by showing the co- and cross-polar radiation patterns. The co-polar radiation pattern is the radiation pattern of the wanted polarization, and the cross-polar radiation pattern is the radiation pattern of the unwanted and opposite polarization. The co and cross polar behavior is often quantified using the co/cross polar ratio (20log(co/cross)) and expressed in dB.

The relationship between the axial ratio and the co/cross polar ratio is shown in *Figure 9*.

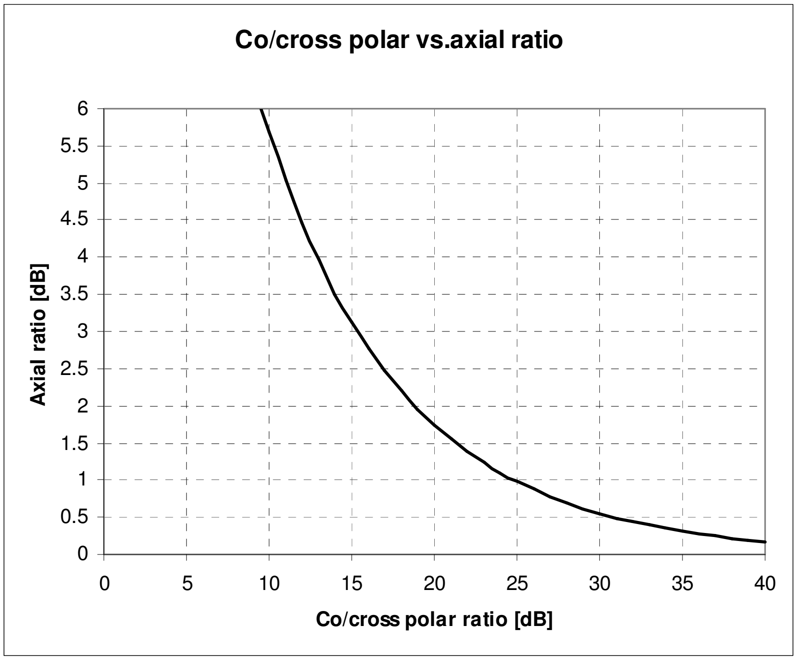

Figure 9: *Co/cross polar ratio versus axial ratio*

Bandwidth

Another important parameter of an antenna is the bandwidth it covers. Most of the time only impedance or return loss bandwidth is specified. However, it is important to realize that several other definitions of bandwidth exist: directivity bandwidth, polarization bandwidth and efficiency bandwidth. Directivity and efficiency are often combined to gain bandwidth.

Impedance/return loss bandwidth:

This is the frequency range over which the structure has a good impedance matching with respect to a certain reference impedance.

The impedance bandwidth depends on a large number of parameters related to the patch antenna element itself like quality factor Q and the type of feed used. The plot in *Figure 10* shows the return loss bandwidth of a patch antenna. The impedance bandwidth of a square, half wave patch antenna is typically limited to 1 to 3% and this is a major disadvantage of this type of patch antenna.

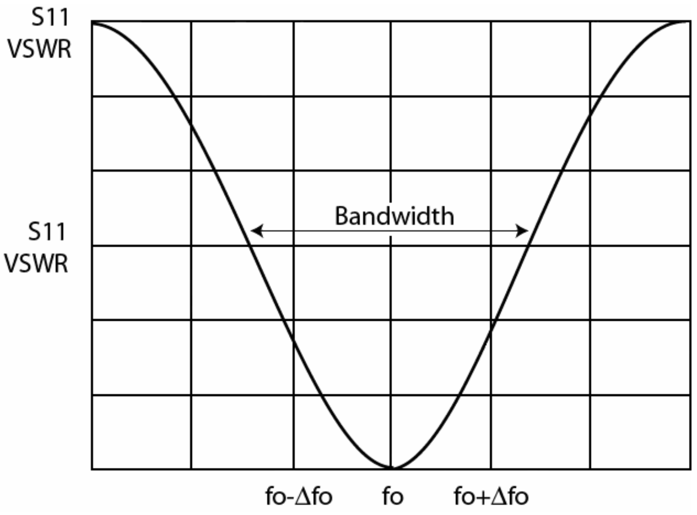

Figure 10: *Impedance bandwidth definition*

Keep in mind that impedance bandwidth can be defined in a couple of ways and that these do not forcibly mean the same thing: VSWR = 2:1, S11 <–10 dB or the maximum real impedance divided by the square root of two [Z(Re)/√2] bandwidth.

Directivity/gain bandwidth:

This is the frequency range where the antenna meets a certain directivity/gain requirement (like a 1 dB gain flatness).

Efficiency bandwidth:

This is the frequency range where the antenna has a defined efficiency.

Polarization bandwidth:
This is the frequency range where the antenna maintains a suitable co/cross ratio.

Axial ratio bandwidth:
This bandwidth is related to the polarization bandwidth and this number expresses the quality of the circular polarization of an antenna.

Alternative Feed Types

A classic way to feed a patch antenna is by using a coaxial probe or connector mounted at the appropriate impedance point and we will look at a couple of alternate ways to connect to a patch. Since in most patch antennas, the impedance bandwidth is much smaller than the radiation bandwidth, we will also look at some techniques to increase the bandwidth.

While the probe feed discussed so far has a bandwidth of only a couple %, it is still very useful for a lot of applications like GPS and WLAN.

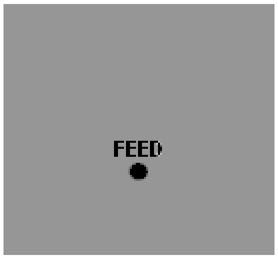

Figure 11: *Probe fed patch*

Another way to connect to the patch is a microstrip line at the edge of the element as shown in *Figure 12*.

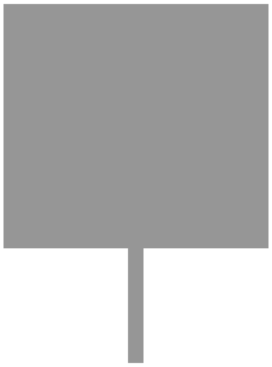

Figure 12: *Microstrip line fed patch antenna*

With this type of feed, impedance transformation to a useful value is needed as the impedance near the edge of the patch is quite high (a couple hundred Ω typical).

The advantage of this structure is the ability to place circuitry near the elements on the same substrate and avoid a multi-layer board. Also, elements can be connected in parallel in the same plane to form an array.

The impedance transformer itself tends to radiate and may distort the radiation pattern of the antenna.

A nice solution is a combination of the antennas from *Figures 11 and 12* and shown in *Figure 13*.

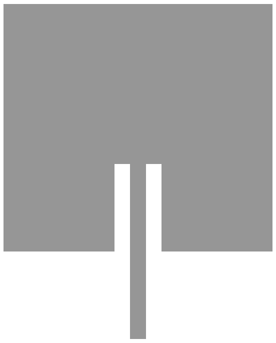

Figure 13: *Inset microstrip line fed patch antenna*

We keep the microstrip feed from *Figure 12* and create an inset to find the same impedance point from *Figure 11*. The gaps distort the radiation pattern of the element, but it is well worth the advantage of being able to connect a standard impedance circuitry straight to the element.

As discussed before, the impedance bandwidth of a basic patch is a couple % at best. The radiation bandwidth is usually much larger and can be up to 50%. Aperture coupling to a patch is a classic impedance bandwidth enhancement technique. The aperture coupled patch has a slot cut in the ground plane under the radiating element as shown in *Figures 14 and 15*. The slot is excited with a microstrip or stripline transmission line over the slot on the opposite side of the ground plane.

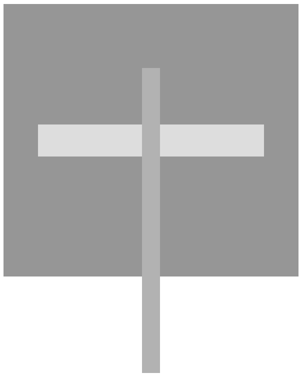

Figure 14: *Aperture coupled patch antenna*

The microstrip fed aperture coupled patch may suffer from a reduced front to back ratio. A stripline feed avoids this: the feed line is 'captured' between two ground layers. A cross section of a stripline fed, aperture coupled patch is shown in *Figure 15*. Impedance bandwidths of 10% can be readily achieved but this structure tends to be a bit more challenging to design.

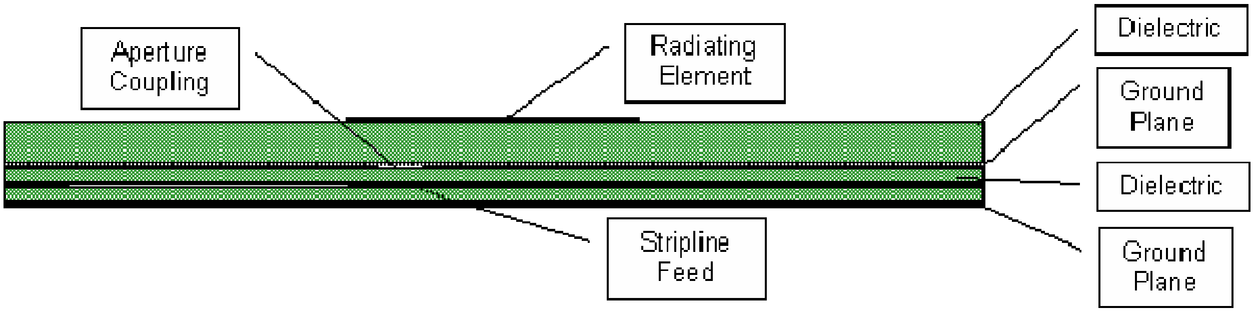

Figure 15: *Cross section of the aperture coupled patch antenna*

The Stacked Patch

Two patches can be vertically stacked and built like a multi layer printed circuit board. Vertically stacking two patches creates a dual band or a wide band patch antenna.

There are three ways to connect to this antenna:

- Connecting to both patches individually (dual band)
- Connecting to the upper patch only: series fed (dual band)
- Connecting to the lower patch only: shunt fed (wide band)

Connecting to both patches is a useful technique to create a dual band patch with separate feeds for each band. The required volume is considerable lower than when using two separate patch antennas for each band. The antenna itself acts as a diplexer, eliminating the need for an additional discrete diplexer. These features effectively reduce the overall system cost.

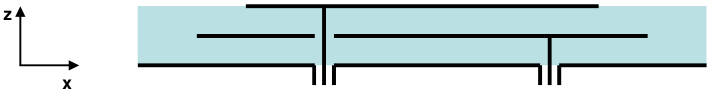

Figure 16: *Stacked patches with dual feed*

Feeding the upper patch only (series feed): this is a classic technique to create a dual band antenna with a single feed. Typically, the lower frequency band uses the lower (and larger) patch while the upper frequency band uses the upper (and smaller) patch. At the lower frequency, the leaky cavity between the lower patch and the ground plane resonates while the leaky cavity between upper patch and lower patch is electrically short circuited because it is off-resonance (the off-resonance impedance of patch antennas is effectively zero). At the higher frequency, the leaky cavity between the upper patch and lower patch resonates while the leaky cavity between lower patch and the ground plane is electrically short circuited because it is off-resonance. This is illustrated in the impedance versus frequency plot in *Figure 18* and the input reflection versus frequency plot in *Figure 19*. It is important that the upper patch is sufficiently smaller than the lower patch in order to avoid fringing field coupling between the two patches. This implies that the frequency bands should be separated by at least 5 to 10%.

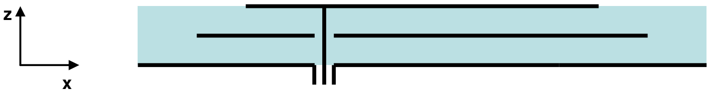

Figure 17: *Series fed stacked patches*

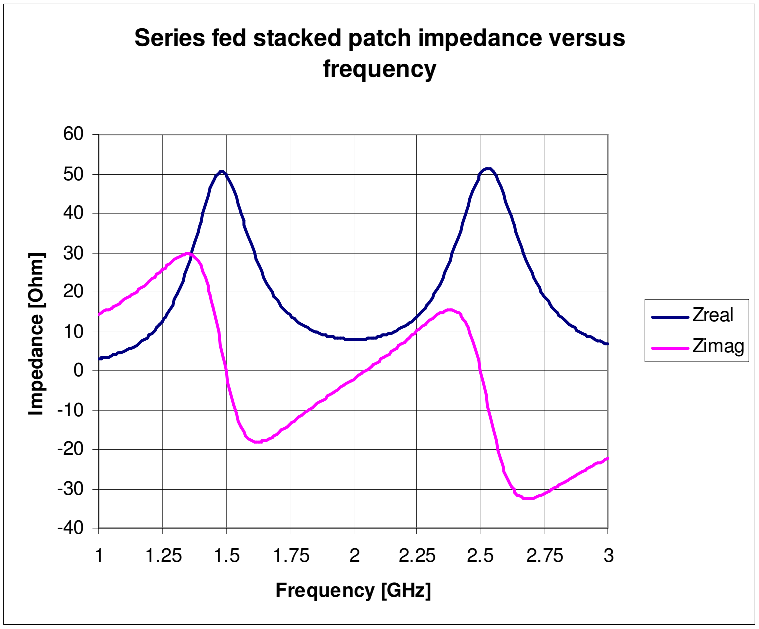

Figure 18: *Series fed stacked patch impedance behavior versus frequency*

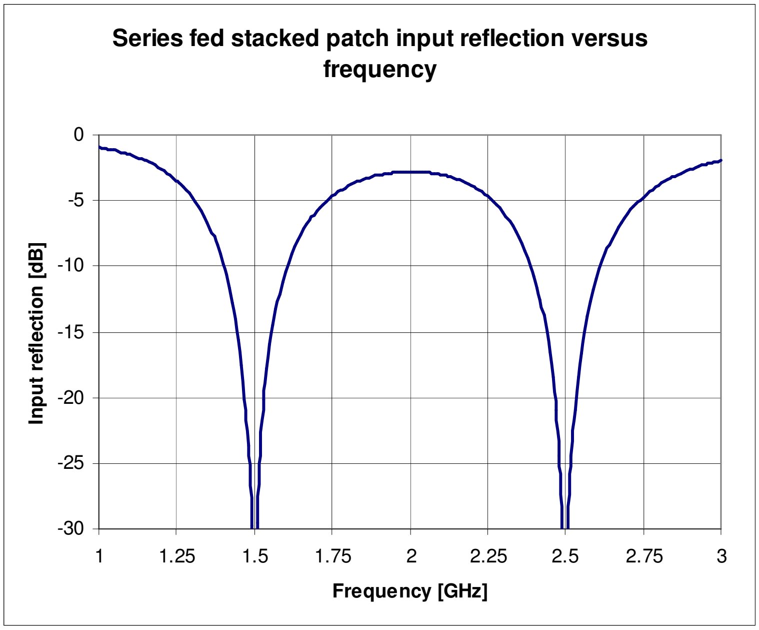

Figure 19: *Series fed stacked patch input reflection versus frequency behavior*

Feeding the lower patch only (shunt feed): this is a classic technique to create a wide band (3 to 10%) patch antenna where each of the two vertically stacked patches covers a sub-band. Dual frequency operation does not work very well with this configuration because the upper patch is electromagnetically coupled with the lower patch. This puts a constraint on the dimensions of the patches making this a wide band rather than dual band structure.

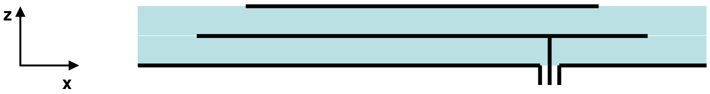

Figure 20: *Shunt fed stacked patches*

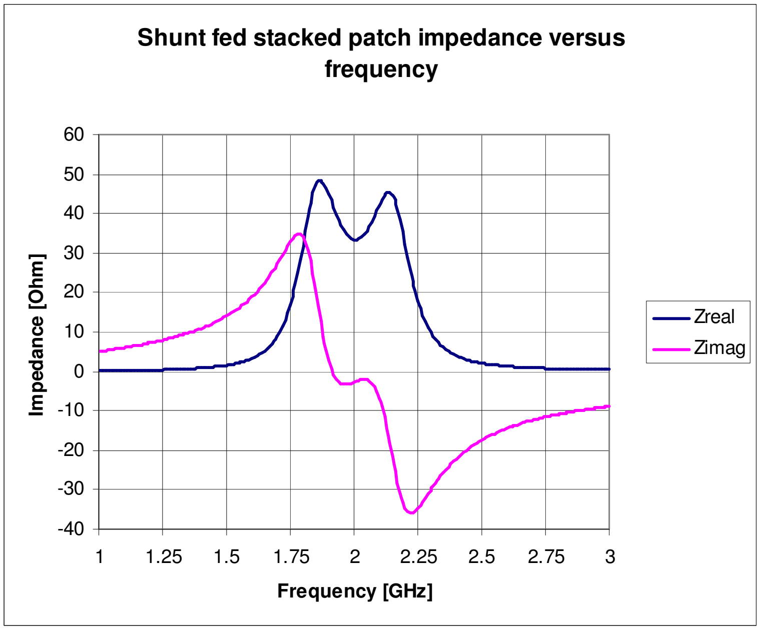

Figure 21: *Shunt fed stacked patch impedance behavior versus frequency*

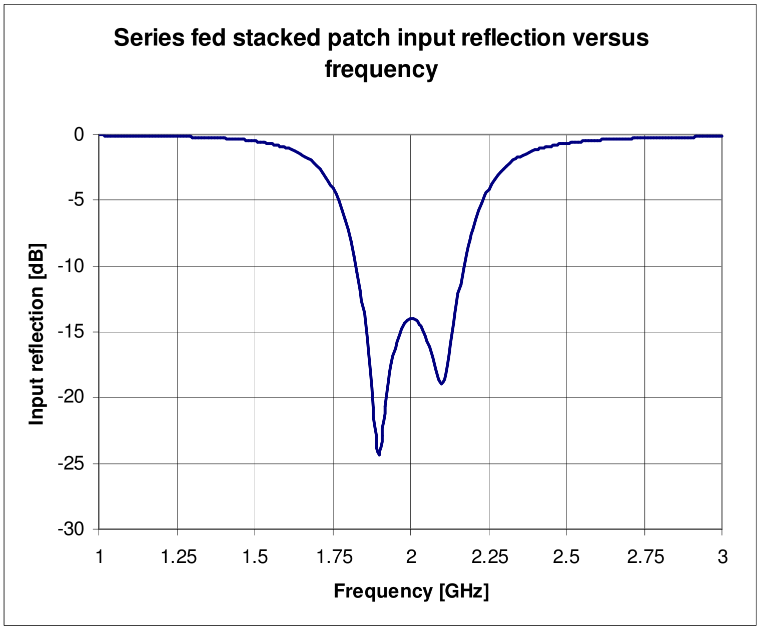

Figure 22: *Shunt fed stacked patch input reflection versus frequency behavior*

Series fed patches work very well (and only then) when the two bands are well separated and the antennas present an effective short at each other's bands of operation. Shunt fed patches work well (and only then) when both resonances are within a couple % of each other.

Higher Modes

So far, we've been talking about the fundamental TM10 mode. But, patch antennas are resonators and inherently exhibit higher modes.

Only a few TM modes are potentially useful and the other useful ones in a rectangular patch are TM20 and TM30. Other modes exist but result in exotic radiation patterns and have little -if any- practical use.

The radiation pattern cross sections of antennas operating in TM10, TM20 and TM30 modes have been plotted in *Figure 23*.

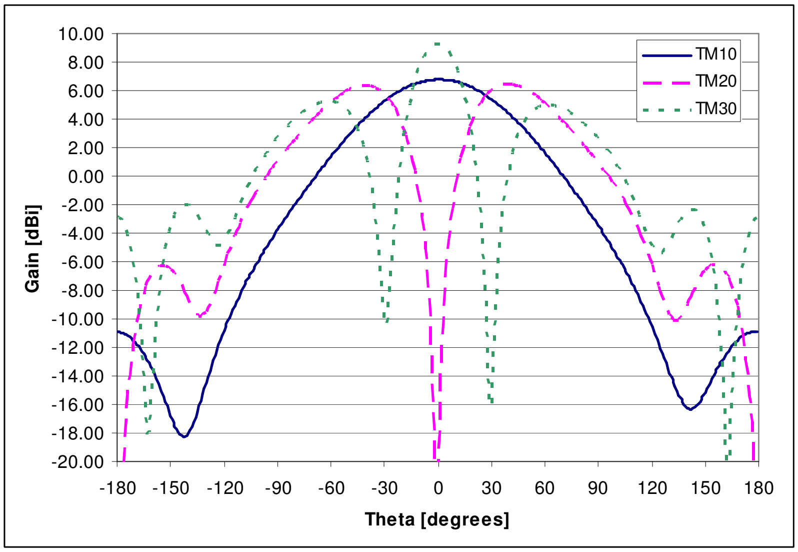

Figure 23: *Radiation patterns of higher rectangular patch modes*

This plot shows that the fundamental mode has one main lobe in broadside, the TM20 mode has two lobes symmetrically around broadside with a radiation null in broadside and the TM30 mode has three lobes: one in broadside and two symmetrically next to the broadside lobe.

These are for a rectangular patch only and differently shaped patch antennas exhibit other mode behavior and associated radiation patterns. Another excellent example is the round patch antenna shown in *Figure 24*:

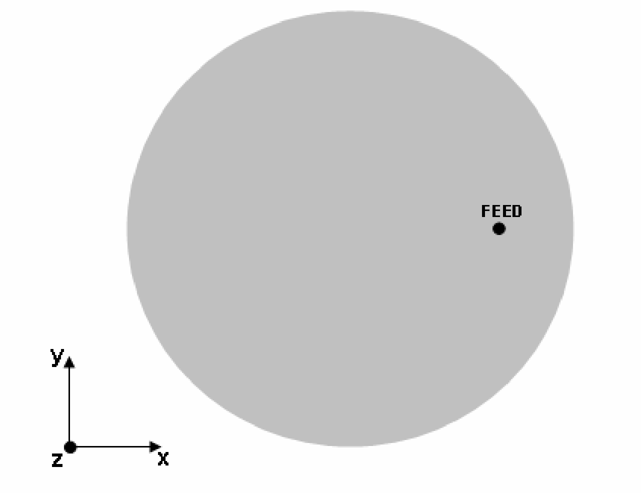

Figure 24: *Probe fed circular disk patch antenna*

The useful three modes of a round patch are TM11, TM21 and TM31. The radiation pattern cross sections are shown in *Figure 25*.

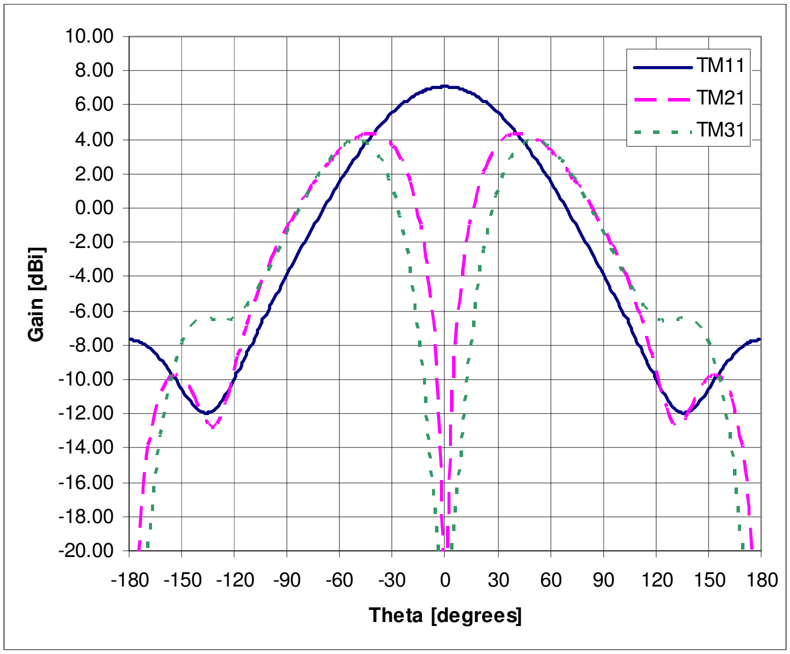

Figure 25: *Radiation patterns of higher circular disk patch modes*

The fundamental mode, TM11, radiates like a square patch operating in TM10. The second mode, TM21, radiates like a square patch operating in TM20. The third mode, TM31, radiates different from the rectangular patch: there is no broadside lobe.

Tuning higher modes tends to be a bit of a challenge relative to fundamental mode tuning because parasitic effects such as cross polar behavior and feed reactance are more problematic. The higher the mode, the more complex tuning is going to be.

Summary

In this article, some of the basic properties of linear and circular polarized patch antennas have been discussed. A basic set of specifications has been defined allowing the reader to understand and write a set of requirements for a specific application. A couple of patch antenna feeding techniques have been described. The stacked patch configuration has been introduced and the higher mode behavior of patch antennas has been explained.

Besides the patch antennas covered here, many more design options and different implementations are possible. Coverage of these alternatives is beyond the scope of this article, but they should be considered during the specification and development phases of the antenna.

UNITED STATES PATENT OFFICE

2,378,663

RADIO RECEIVER

George O. Striker, Chicago, Ill., assignor to Zenith Radio Corporation, Chicago, Ill., a corporation of Illinois

Application January 16, 1942, Serial No. 426,991

43 Claims. (Cl. 250—20)

This invention relates to radio receivers and particularly to receivers adapted to operate on a plurality of bands.

One of the objects of the invention is to provide a portable radio receiver which is provided with a plurality of antennae suitable for different wave bands and for use under different circumstances with relation to different locations and different conditions as to man-made static and other forms of interference.

A further object of the invention is to provide a radio receiver with a short wave loop antenna which may be located at positions relatively remote from the receiver.

A further object of the invention is to provide means for tuning the loop to adapt it for the reception of signals in different bands.

A further object of the invention is to provide a radio receiver with a plurality of antennae with means whereby the preparation of one antenna for use renders another antenna inoperative.

A further object of the invention is to provide a radio receiver having a fish-pole antenna and switch means controlled thereby connecting and disconnecting said antenna to the input of the receiver and for connecting and disconnecting another antenna from the input of the receiver.

Other objects, advantages and capabilities of the invention will appear from the following description of a preferred embodiment thereof, taken in conjunction with the accompanying drawings, in which:

Figure 1 is a perspective view showing the manner in which the portable radio receiver may be used by a railroad passenger;

Fig. 2 is a front elevational view of the receiver, the front cover being opened;

Fig. 3 is a rear elevational view, the rear cover being removed to show internal parts;

Fig. 4 is a sectional detail taken on the line 4—4 of Fig. 3 showing the telescoped fish-pole antenna in cross-section and associated elements in elevation;

Fig. 5 is a front view of the mechanism shown in Fig. 4;

Fig. 6 is an elevational view of the two-loop antenna structure, a cover of the short wave loop being removed and an associated part thereof being shown in section;

Fig. 7 is a fragmentary plan view thereof on a somewhat larger scale;

Fig. 8 is a wiring diagram of the receiver;

Fig. 9 is a fragmentary rear view of the receiver with the rear cover removed, showing a modified form of fish-pole antenna;

Fig. 10 is an elevational view partly in section of such fish-pole antenna in collapsed form; and

Fig. 11 is a view similar to the left-hand side of Fig. 6 showing a modified form of short wave antenna.

Referring to the drawings, the radio receiver as a whole is contained within a case **20** which is provided with a hinged front cover **21**. When the front cover **21** is opened, music and other broadcast material may be emitted from the loud speaker **22**.

Adjacent the loud speaker **22** is a panel **23** which serves as a mounting for tone controls **24**, a tuning control **25**, and a volume control **26**. The tone controls **24** open and close the four switches **27** in Fig. 8 to effect control of the tone. The tuning control **25** controls a gang of condensers **28**, **29** and **30** for tuning the RF input circuit, mixer input circuit, and oscillator circuit, respectively (Fig. 8).

The volume control **26** controls the double-pole single-throw switch **31** (Fig. 8), and the volume control **32** also shown in that figure. The tuning control actuates not only the gang of condensers but also the pointer **33** of the dial **34**.

The dial **34** comprises indicia **35** corresponding to the broadcast band and five sets of indicia **36** which correspond to five short wave bands, for example, the 16-meter, the 19-meter, the 25-meter, the 31-meter, and the 49-meter bands.

Adjacent the dial **34** is an escutcheon plate **37** which carries a series of projecting switch buttons **38**, **39**, **40**, **41**, **42** and **43**, corresponding to the broadcast bands just referred to.

As best seen in Fig. 2, the escutcheon plate **37** bears opposite these buttons the name of the corresponding band and also indicia adjacent the buttons indicating when the best reception is received with that band. Thus, the best reception of the 49-meter band is in the evening, with the 31- and 25-meter bands in the afternoon and evening, the 19-meter band all day, and the 16-meter band in the morning.

The double-pole single-throw switch **31** controls the supply of electrical energy to the tubes of the receiver. This energy may be supplied by A and B batteries **44** and **45** (Fig. 8) carried in the receiver case or it may be supplied by the plug **46** which may be inserted in any available wall receptacle, the power pack associated therewith being arranged for A. C. and D. C. operation. This power pack includes a rectifier tube **47** and the filter instrumentalities illustrated in Fig. 8.

The receiver may be changed over from battery to power line operation by means of a four-pole double-throw switch **48** shown in power line position in Fig. 8.

The band switch buttons **38** to **43** constitute the outer ends of axially movable switch bars bearing the same numbers and shown in Fig. 8. In this figure two views of each switch bar are shown in relatively inverted relation. Thus, if one of the switch bars were actuated in Fig. 8, then the upper showing of that bar would be displaced upwardly while the lower showing of that bar would be displaced downwardly. The black parts of the switch bars represent insulation and the white parts conducting material.

The bars **38** to **43** are associated with a locking bar **49** of known type shown diagrammatically in Fig. 8. This locking bar is so arranged that it holds any bar which is displaced inwardly in its inward switching position. The bar is so arranged that it is actuated to releasing position by the inward movement of another bar. Consequently, only one of the band switches **38** to **43** is operative at any time.

The receiver may suitably be a superheterodyne receiver, tube **50** being a radio frequency amplifier, tube **51**, the mixer, tube **52**, an intermediate frequency amplifier, tube **53**, a detector and audio amplifier, tube **54**, a power amplifier, and tube **55**, the oscillator tube.

The receiver is provided with a plurality of antenna structures which will now be described. For broadcast pickup, a loop antenna **56** of the type described and claimed in Patents Nos. 2,164,251, 2,200,674, 2,237,260, and 2,250,387, issued to Eugene F. McDonald, Jr., may be employed.

The loop **56** is enclosed within a suitable nonconductive enclosure **57** which is hinged to plate members **58**. These plate members **58** carry suction cups **59** whereby the loop may be mounted on the glass window **60** of a conveyance. This conveyance may, for example, be a steel railroad car, a bus, an airplane, or an automobile. Of course, the invention is not intended to be limited to a conveyance since its antenna may be used to great advantage in a steel or metallized house, or it may be used irrespective of any enclosure whatsoever. Normally, the suction cups **59** do provide a very simple quickly attachable and detachable means for supporting the loop **56** on or near a dielectric wall such as a pane of glass in an enclosure which is constituted for the most part by walls of conducting material. It is within the scope of my invention to provide one or more suction cups to support loop **56**.

The ends of loop **56** are connected to two leads **61** and **62**, lead **62** appearing in Fig. 8 as the outer conductor of a coaxial cable having a center conductor **81**. For the purposes of the broadcast loop **56**, it is important that the distributed capacity between the leads **61** and **62** should be maintained low and should be maintained substantially constant. For this reason the conductor **81** and its shield **62** are located along one edge of a stout ribbon **82** and the conductor **61** is located along the opposite edge of this ribbon. This ribbon is relatively broad and stiff so that the spacing between the conductors at the opposite sides is maintained substantially constant. The latter lead is connected to a small loading coil **63** on a five-prong plug **64**. The five prongs are shown as ringed dots in the upper left-hand corner of Fig. 8. The conductor **61** is connected to one prong. The coil **63** is connected to another. A tap on this coil is connected to still another prong.

On the receiver is mounted a three-position switch **65** which in one position shorts the upper part of the coil **63** and in another position introduces a small capacity **66** across the leads **61** and **62**. In its intermediate position the switch **65** has no effect on the inductance or capacity of the circuit including the loading coil **63** and the loop **56**. The purpose of the switch **65** is to introduce a slight correction for improving the tuning of the loop **56** which may be impaired by mounting the loop too near the edge of a steel window, for example, or from some other cause. The capacity **66** may suitably be constituted by a few turns of wire around the conductor leading to conductor **61** as is illustarted in Fig. 8.

The housing **57** also contains a coil **90** of a few turns in close proximity to the loop **56**, the ends of the coil **90** being connected to terminals **91** and **92**. In the case of a semi-permanent installation, for example in the case of a sojourn at a country home, it may be desirable to operate with an outside aerial which may be connected to the terminal **91**, the terminal **92** being grounded. It will thus be seen that the coil **90** is coupled to the loop **56** and that the operation for broadcast reception with an outside aerial is attained in a remarkably simpler manner.

For short wave reception the loop antenna **56** is no longer suitable. An antenna having a low inductance and capacity is required. In accordance with the present invention, I provide a short wave loop antenna **67** which consists essentially of a few turns of wire extending around a U-shaped dielectric tube **68**. The tube **68** has its ends mounted in a housing **69** which is hinged to the plates **58** as best seen in Fig. 6.

If the loop **67** were not tuned separately from the receiver and were located at a point remote from the receiver, the inductance and capacitance of the connections between the loop and receiver, especially at high frequencies, would seriously mistune the loop. In fact, such a loop with its connections to the receiver would probably be resonant at a relatively low frequency. By providing a small degree of coupling between loop **67** and the receiver input circuit it is possible to eliminate the mistuning effect of the connections sufficiently that the loop **67** may be tuned substantially independently of the receiver even at high frequencies. In accordance with this invention, adjustable tuning means is provided at the loop to tune the loop to any desired frequency. Such an arrangement is shown in Fig. 8. Opposite ends of the loop **67** are connected across a condenser **70** which is arranged to tune the loop to a desired frequency within one of the short wave bands. A three-position switch **71** is arranged to cut in a condenser **72** or a condenser **73** into parallel connection with the condenser **70** so as to tune the loop for two other short wave bands of longer wave length.

When using a short wave loop such as loop **67** it is even more desirable than with the broadcast loop **56** to provide a relatively long transmission line for connecting the loop remotely to the receiver input so that the loop may be placed in a position removed from the receiver. This is so because at high frequency the conductors of the receiver itself if too near the loop, shield or damp the loop even more so than at lower frequencies and render it less effective to transmit a signal to the receiver input. At the same time, the use of such a line becomes more difficult at high frequencies because of radiation loss from and radiation pickup on the transmission line itself. Also, the problems of shunt and stray capacity of the transmission line, discussed in connection with the broadcast loop 56, become more troublesome. For the purpose of transmitting signals intercepted by the short wave loop 67 and transferring the same to the receiver located remotely from the antenna, and more specifically for transferring intercepted signals to a control grid of the mixer tube 51, there is provided a link circuit extending in space from the loop 67 to the receiver and comprising a first coupling coil 78 coupled to the loop 67, a pair of conductors 62 and 81, a switch 100, and three coupling coils 74, 75 and 76, all connected in series relation. The coil 78 suitably comprises a single turn of wire positioned closely to the loop antenna 67 and preferably has a common point therewith. The loop antenna 67 and the coil 78 thus form a step down transformer.

The switch 100 is closed when using the receiver with the short wave antenna 67 and is actuated by the fishpole antenna 93 as will be explained hereinafter. The coils 74, 75 and 76 are located at the receiver and coupled to coils 42*a*, 41*a* and 40*a*, respectively, which can be connected in circuit with the tank circuit comprising the secondary winding of transformer 101 and variable condenser 29 for the purpose of applying the signal intercepted by the antenna 67 to a control grid of the mixer tube 51. The variable condenser 29 tunes the tuned circuit 101, 29 to the same signal frequency as that to which the loop 67 is tuned. Tuning of the receiver input as well as the loop increases the selectivity of the set in an amount proportional to the product of the quality factors of the two tuned circuits. This is desirable for best operation of a superheterodyne receiver.

Since the coils 74, 75 and 76 each have a smaller number of turns than the coils 42*a*, 41*a* and 40*a*, respectively coupled thereto, there is an upwards transformation of voltage therebetween. The voltage transformations, down at the antenna and up at the receiver at the opposite ends of the link circuit results in good energy transfer and yet permit the transmission line to operate at a lower voltage thereby reducing the effect of the shunt and stray capacity of the line. Furthermore, this transformation produces a better impedance match between the high impedance tuned antenna circuit and the untuned transmission line, and between the line and the high impedance tuned input circuit of the receiver. In the specific embodiment of the invention shown, the loop antenna 67 is arranged to operate on the 31-meter, the 25-meter, and the 19-meter bands, these being the bands controlled by the switch bars 40, 41 and 42, respectively. It will, however, be understood that any desired number of condensers may be provided so as to be brought into parallel relation with the condenser 70 and the windings 74, 75 and 76 should be likewise increased in number.

Thus, I may provide, instead of the switch 71, a five-position switch, and provide two condensers in addition to 72 and 73, arranged to be connected in parallel with the condenser 70 by the five-position switch. In addition, two windings in series with the windings 74, 75 and 76, would be provided in the same relation with the coils associated with the bars 39 and 43 as the coils 74, 75 and 76 bear to the coils associated with the bars 42, 41, and 40, respectively.

The switch 71 is mounted on the housing 69 and is provided with a projecting button 77 (Fig. 6). It will, of course, be understood that suitable indicia (not shown) is associated with the button 77 so as to indicate the particular short wave band for which the loop 67 is tuned by the switch 71.

The condensers 72 and 73 are adjustable trimmer condensers of appropriate value. The condenser 70 is preferably variable by means of a manually operable member 79. The manually operable member may consist, for example, of a small rough edged wheel of insulating material, the center of which is operatively connected to the condenser 70.

The edge of the wheel 79 projects out of the housing 69 so that it can be actuated manually to provide a slight adjustment of the condenser 70. This slight adjustment corrects for variable capacity effects introduced by variable mounting of the loop relative to conductors such as the body of a steel car.

The connection of the loop 67 and the coil 78 of the link circuit to the receiver will now be described in detail. The connections comprise a common conductor 62 which is a shield. This shield extends to the plug 64 where it is connected, as previously indicated, to one end of the loading coil 63 and to the fifth prong of the plug. Within this shield is a conductor 81 which is connected to the other end of the coil 78. This conductor is connected to the fourth prong of the plug 64. The shield 62 and conductor 81 form a coaxial line. Of course two separate wires may be used, if desired, but the shielded line provides one of the simplest means of achieving the desired characteristics of the transmission line, namely, low signal radiation loss and stray radiation pick up, and relatively low shunt capacity. Of importance, for obtaining suitable signal pickup in a shielded structure, is the tuned loop antenna winding 67 which is coupled through an untuned link circuit to the input circuit of a receiver tuned to the same frequency as is the loop antenna.

The composite link circuit includes the first coil 78 on one end of the conductors 62, 81 and on the other end the serially connected coils 74, 75 and 76 which, for purposes of analysis, may be grouped and considered as a second coil serially connected with said first coil 78 through the elongated conductors 62, 81 comprising, preferably, the co-axial cable, as shown in Figure 6.

Coil 78 is mounted near to and coupled to antenna 67 directly through transformer action, the winding of antenna 67 serving as one element of the transformer, and coil 78 serving as the other element of the transformer. This type of coupling is preferred, inasmuch as a minimum number of circuit elements is necessary and efficiency of energy conversion is high.

Of importance in short-wave reception, is that tuning of the antenna 67 and tuning of the input circuit of the receiver results in high selectivity and high image ratio. This is especially desirable at high frequencies.

Furthermore, the particular arrangement of the link circuit with the tuned loop antenna and tuned receiver input circuit results in a decrease in both the inductance at the loop antenna and at the input circuit of the receiver, in accordance with the principles set forth in "Radio Engineer's Hand Book," by Frederick E. Terman, 1943, published by McGraw-Hill Book Company.

Furthermore, inasmuch as the over-all co-efficient of coupling between the tuned loop antenna 67 and the tuned input circuit of the receiver is quite small, the tuned loop antenna 67 is coupled in small degree to the tuned input circuit, as is evidenced by the constructions shown in

Figs. 6, 8 and 11. It is remembered that the co-efficient of coupling between two circuits is a ratio and is defined as the ratio of the mutual inductance actually present between two windings to the maximum possible value that can occur. In accordance with this accepted definition of the co-efficient of coupling, the magnitude of the coupling between loop antenna **67** and adjacent link circuit coil **78** in Figs. 6 and 11 is in the range of .15 to .25.

The co-efficient of coupling between the tuned input circuit of the receiver and the adjacent link circuit coil, comprising, in fact, three coils **74**, **75** and **76**, has as its maximum possible theoretical magnitude one-third or .33, inasmuch as the flux from only one of such coils **74**, **75** and **76** threads the magnetically coupled input circuit of the receiver. As shown by Fig. 8, the secondary coils **40A**, **41A**, and **42A** are, respectively, close to their associated iron cores, and primary coils **76**, **75** and **74** are spaced a substantial distance from the corresponding secondary coils and cores. Therefore, the co-efficient of coupling between each of the coils **76**, **75** and **74** and its associated secondary coil is substantially less than unity, with the result that the co-efficient of coupling between the link circuit coil comprising serially connected coils **74**, **75** and **76** is substantially less than the possible theoretical maximum magnitude of .33.

In accordance with a commonly accepted definition of "loose" and "tight" coupling, as set forth in the above-mentioned "Radio Engineer's Hand Book," these recited magnitudes of the various coupling co-efficients of .15 to .25 and .33 neither correspond to "tight" coupling nor to "loose" coupling, inasmuch as such publication states that closely coupled coils usually have a coupling co-efficient of .5 or greater, and loosely coupled coils have a coupling co-efficient of .01 or less. Thus, these two magnitudes of .15 to .25 and .33 fall within a range which, for purposes of this specification, corresponds to a state of medium coupling.

The short-wave loop antenna shown herein is thus not tightly coupled to the input circuit of the receiver upon consideration that the over-all coupling is the product of the individual coupling co-efficients and which has a maximum product of .25×.33 or .0825. Of course, this actual magnitude of .0825 for the over-all coupling co-efficient is the maximum theoretical magnitude and, for the reasons explained, is smaller in actual physical receivers embodying apparatus having the precise arrangement of elements shown herein.

This small degree of coupling, which gives efficient energy transfer consistent with high selectivity and good image ratio, is desirable not only for the reasons stated above including making it possible to tune the loop **67** substantially independently of the receiver but also because it makes possible the use of a critical amount of coupling which by definition is the condition for maximum energy transfer. In accordance with the present invention, I also provide a fish-pole or extensible rod antenna **93** which is normally housed in telescoped and unerected position, as shown in Fig. 3, the fish-pole antenna being then located in the rear of the housing. To render the fish-pole antenna operative, the rear door of the receiver housing is opened and the telescoped fish-pole antenna **93** is swung into vertical position, that is, the position in which it is shown in dotted lines in Fig. 3. For this purpose the lowermost section of the fish-pole antenna **93** is rigidly carried on a lever **94**.

The lever **94** is pivotally mounted on a bracket **95** secured to one side of the case **20** of the receiver. When the fish-pole antenna **93** is erected, its lowermost section is brought into registry with two semi-circular openings **96** in the upper wall of the case **20** and on the upper edge of the rear door thereof so that this door may now be closed, leaving the fish-pole antenna projecting upwardly from the case in the vertical direction. It will, of course, be understood that the fish-pole antenna may be pulled out or extended in normal manner, illustrated in Fig. 9, with respect to a modified arrangement of fish-pole antenna.

Referring to Figs. 4 and 5, it will be readily understood that when the lever **94** is swung by the movement of the fish-pole antenna **93** into erected position, one end of the lever **94** engages a projection **97** and moves it upwardly, thus displacing contacts **98**, **99** and **100** upwardly. These contacts are elements of the three switches **98**, **99** and **100** shown in Fig. 8. These switches are shown in Fig. 8 in the condition in which they are after the fish-pole antenna has been erected. It will be understood that when the fish-pole antenna is again unerected or turned into horizontal position, the switches **98** and **99** assume their different positions and the switch **100** becomes closed.

In the embodiment of the invention shown in Figs. 9 and 10, a different fish-pole antenna **120** is employed. This fish-pole antenna has a lower section **121** which is fixedly mounted within the case **20** of the receiver. As shown in Figs. 9 and 10, the fish-pole antenna comprises a plurality of sections which can be telescoped together. When fully telescoped, the knob **122** of the fish-pole antenna projects from the upper side of the case **20** as shown in dotted lines in Fig. 9. The fish-pole antenna may, of course, be extended fully or to a desirable degree by merely grasping the knob **122** and pulling it upwardly.

The innermost section of the fish-pole antenna consists of a rod **123** which is somewhat longer than the other sections of the fish-pole antenna. Consequently, when the fish-pole antenna is fully telescoped back into the case **20**, the rod **123** projects beyond and below the lowermost section **121**. In this embodiment of the invention the switch elements **98**, **99** and **100** are adapted to be actuated by the movement of a projection **97'**, this projection having a portion extending below the fish-pole antenna so as to be actuated by the rod **123**. The projection **97'** is biased upwardly by suitable springs.

It will readily be understood that when the knob **122** is moved upwardly from its normal position and when the knob **122** is returned to its normal position, the same switching operation effected by the erection and reclining of the fish-pole antenna **93** will take place.

The loop antenna shown in Fig. 11 differs from the loop antenna **67** primarily in that it consists of two turns **124** of relatively stiff wire. This wire is sufficiently strong so that it does not need to be enclosed in a dielectric tube as shown in the previously described embodiment.

The two turns **124** are supported where they enter the housing **69** by means of two bushings **125** of suitable dielectric material. The two loops **124** are further secured together preferably at a position remote from the housing **69** by means of a suitable block or spacer **126** of insulating material. The remainder of the elements associated with the loops 124 may be precisely the same as in the previously described embodiment.

The operation is as follows: To prepare the receiver for battery operation, the four-pole switch 48 is thrown to the right, as viewed in Fig. 8, and the double-pole single-throw switch 31 is closed, supplying electrical energy to the tubes. On the other hand, if it is desired to operate from power lines with A. C. or D. C. current, the plug 46 is plugged into a suitable outlet, the switch 48 is thrown to the left, as viewed in Fig. 8, and the switch 31 is used as an "on and off" switch as it was when the receiver was battery operated.

For operation in the broadcast band, the antenna employed is selected in accordance with the location. At the beach or at a football game, it is preferred to employ the fish-pole antenna 93 for this puropse, whereas on a train or in a metal airplane, or indeed in any partially shielded structure or in any location where there is a large amount of man-made static, better results will be obtained with the loop 56.

Operation with the loop 56 will first be described. The loop 56, together with the loop 67, is mounted by means of the section cups 59 at a suitable location on a train window as shown in Fig. 1. Considerable improvement in reception can usually be obtained by slight changes of the mounting position on the window and changes of orientation of the loop relative to the window.

The broadcast bar 38 is pushed inwardly and tuning is effected by means of control 25, the volume being controlled by the button 26 which actuates the switch 31. The tuning is indicated on the scale and indicia 35, this being the broadcast scale.

Reception is improved by orientating the loop 56 relative to the plates 58 whereby the loop is brought into the best plane for reception. Reception may be improved further by operating the switch 65 into the best of its three positions.

Since the fish-pole antenna 93 is in its unerected position, the switches 98 and 99 are in their other positions from those shown in Fig. 8, switch 100 being closed.

Consequently, conductor 61 is connected directly to the control grid of the RF amplifier tube 50. The loop is tuned by the condenser 28 of the gang of condensers, the other side of the condenser 28 being connected through loading coil 63 to conductor 62.

Since the broadcast bar 38 has been actuated, its upper portion in Fig. 8 is displaced upwardly and its lower portion in that figure is displaced downwardly. As a result of the upward displacement of the bar 38, the high side of the secondary of the radio frequency transformer 101 is connected through condenser 102 to a grid of the mixer tube 51. Unless the bar 38 is pushed inwardly, this connection is not made and consequently no broadcast signal can pass from the radio frequency tube 500 to the mixer tube 51.

It may be noted that the condenser 102 is relatively large being, for example, a .02 microfarad condenser. On the other hand, the condenser 103 which connects the high side of the secondary of the transformer 101 to the condenser 102 is very small, having a capacity of around 15 micro-microfarads. Thus at broadcast frequencies the condenser 103 is not large enough to couple the secondary of transformer 101 to the mixer tube 51. Condenser 103 is used in short wave reception as will be described. The actuation of the bar 38 shorts the condenser 103. The actuation of the bar 38 tunes the oscillator tube 55 to an appropriate frequency band. The grid of this tube is connected through condenser 104, contacts 105 and 106 to the tank circuit 107, the other side of which is connected to radio frequency ground. Radio frequency ground is determined by condenser 108 which may suitably be a .1 microfarad condenser. The cathode of the tube 55 is connected thereto through condenser 109 which may suitably be a .07 microfarad condenser. The plate of the tube 55 is connected through condenser 110 and contacts 111 and 112 to a coil 113 coupled to the tank circuit 107.

The same circuits are established when an outdoor aerial is employed with the aid of the coil 90.

Employing the fish-pole antenna 93, the erection of the fish-pole or its extension in the case of a fish-pole of the second described variety, moves the switches 98, 99 and 100 into the positions in which they are shown in Fig. 8. The circuit of loop 56 is now broken and signal passes from the fishpole antenna 93 through switch 99, through contacts on the actuated bar 38 up to the tap on coil 114 to radio frequency ground.

Condenser 115 is a trimmer to compensate for variations in fish-pole circuit capacities. The signal energizes the circuit including coil 114 and tuning condenser 28, the high side of which circuit is connected to a grid of the radio frequency tube 50. The oscillator circuit is as previously described.

The fish-pole 93 can also be employed in the case of all the short wave bands. In this connection it is pointed out that when operating on any of the short wave bands, the broadcast bar 38 is in its outer position, so that no broadcast signal from the loop 56 can pass to the mixer as has previously been described. At short wave frequencies the loop 56 is substantially shorted so that substantially no short wave signal passes from tube 50 to tube 51 even though they are coupled at these frequencies through condenser 103.

If the button 43 is actuated, the fish-pole signal passes to coil 43*a*, the low side of which is connected to radio frequency ground. The high side of the coil 43*a* is connected through the unactuated bar 38 and through coupling condenser 102 to a grid of the mixer tube 51. At the same time the high side of the coil 43*a* is connected through the relatively small condenser 103 to the high side of the tank circuit including the secondary of the transformer 101 and the tuning condenser 29. The condenser 29 tunes the signal input circuit of tube 51 in coordination with the tuning of the oscillator circuit. The coil 43*a* thus forms a part of a circuit tuned to the signal frequency.

The actuation of the bar 43 (lower portion in Fig. 8) connects the circuit of the grid of oscillator tube 55 to the upper end of coil 43*b*, the lower end of which (actually a tap) is connected to radio frequency ground.

At the same time the plate of the oscillator tube 55 is connected through condenser 110 and the bar 43 to the coil 43*c* coupled with coil 43*b*, the other end of the coil 43*c* being connected to radio frequency ground (actually the same tap).

The grid of the oscillator tube 55 is connected through condenser 104 and contacts 105 and 116 on the unactuated bar 38 to a condenser 117. The condenser 117 is connected to radio frequency ground by a condenser 118 and it is also connected by contacts 119 and 106 on the unactuated bar 38 to the tank circuit 107. This permits the use of condenser 30 as a band spread tuner. Since this condenser is in series with the small condenser 117 and is shunted by fixed condenser 118, the effect in change of capacity when condenser 30 is varied is, therefore, very small. The oscillator frequency is thus tuned by the variable condenser 30 to give an appropriate oscillator frequency for this band.

Similar results can be obtained with the bars 42, 41 and 40, the associated coils being indicated 42*a*, 42*b*, and 42*c*, etc.

The bar 39 controls an oscillator circuit in precisely the same way as the bars 40 to 43, coils corresponding to 40*b*, 40*c* being designated 39*b* and 39*c*, respectively. The fish-pole signal, however, goes through the coil 39*a* to radio frequency ground. This coil is inductively coupled to a winding 39*d*, thus decreasing the coupling of the fish-pole to the input circuit. The winding 39*d* is connected through the two uppermost contacts on bar 39 (Fig. 8) through condenser 102 to the grid of the mixer tube 51 and through condenser 103, to the tank circuit including the secondary of transformer 101 and the tuning condenser 29.

When the button 38 is not in actuated condition and when the fish-pole antenna 93 is in its unerected position or the corresponding fish-pole antenna 120 is in fully telescoped condition, both the loop 56 and the fish-pole are rendered inoperative. In the first case, the high side of the secondary of the transformer 101 is effectively disconnected and in the second case the switch 99 is opened.

The receiver is now in condition for operation by the loop 67 (or the equivalent loop 124). It is to be noted that the switch 100 is closed when the fish-pole is stowed away. This switch may be omitted if desired since when the fish-pole antenna is in operation, the two loops 56 and 67 are stowed away in the back of the case 20. At the high frequencies for which the loop 67 is suited, this loop is substantially shielded by the other nearby conductors in the case and is not in the least effective. However, in some cases it is preferred to use the switch 100 and if it is used, it must be closed when short wave loop reception is desired.

The loop 67 being mounted on window 60 of a railroad car, for example, it is orientated manually to give best reception and the button 40, 41 or 42 is pushed in accordance with the band which it is desired to receive.

The switch 71 is moved into the corresponding position to select the same band, this switch being located on the housing 69 of the loop 67 as has been previously described.

The receiver is, of course, turned on by the switch 31 on the volume control 26 and tuning is effected by means of the button 25 to bring in the desired station. Control wheel 79 may then be adjusted to tune the loop 67 accurately within the selected band to the station manually selected by button 25. Slight correction for variation of capacity of the loop 67 by reason of varying position on the window 60 is also readily taken care of by actuating the control wheel 79 of the condenser 70.

The signal from the loop 67 is conveyed through the link circuit which includes the coil 78, the leads 82 and 81 and the coils 74, 75 and 76. The signal is transferred from the appropriate one of these coils to the coil 42*a*, 41*a*, or 40*a*, depending upon which of the three buttons 42, 41 or 40 is in the actuated position.

As has previously been explained, one end of each of the coils 42*a*, 41*a* and 40*a* is connected to radio frequency ground and the high sides of these coils are connected, when their respective buttons 42, 41 and 40 are pushed, to the grid of the mixer tube 51 and to the tuning condenser 29 in the manner previously described in connection with short wave operation with the fish-pole antenna.

Although the invention has been described in connection with specific details of preferred embodiments thereof, it must be understood that such details are not intended to be limitative of the invention except in so far as set forth in the accompanying claims.

Having thus described my invention, I declare that what I claim is:

1. In combination, a radio receiver, said receiver having an input circuit, a loop antenna winding spaced a substantial distance from said input circuit, a low impedance untuned link circuit extending between said input circuit and said antenna winding and arranged to transfer radio frequency energy therebetween, said link circuit including a coil having less turns than said antenna winding, means mounting said antenna winding and coil in close proximity to one another such that said antenna winding and coil comprise elements of a transformer, and means for tuning said input circuit to a frequency equal to the frequency at which said antenna winding is tuned whereby radio energy is efficiently transferred between said antenna winding and link circuit and variations of stray capacity of said link circuit produce no substantial effect on transfer of such radio energy.

2. In combination, a radio receiver, said receiver having a plurality of input circuits tunable to the frequency of signals in any one of a plurality of bands in a relatively large frequency spectrum, means for tuning said input circuits, each of said input circuits including a coil, a loop antenna arranged to be mounted remotely from said receiver, means proximate to said loop for tuning it to a predetermined resonant frequency corresponding to a frequency in any one of said plurality of bands, a low impedance untuned link circuit arranged to pass signals in all of said bands and coupling said loop antenna to said coil of each of said input circuits, and means for selectively connecting one of said tunable input circuits to said receiver for the transfer of signals from said link circuit to said receiver.

3. In combination, a portable radio receiver unit having an input circuit, a coil connected in said input circuit for the transfer of energy to said unit, means for tuning said coil to a frequency desirable for operation of said radio unit, a short wave loop antenna arranged to be mounted remotely relative to said unit, means proximate to said loop for tuning it to a predetermined resonant frequency equal to the first mentioned frequency, an untuned link circuit coupling said loop antenna to said coil in said input circuit, said link circuit comprising: a two-conductor cable extending from said loop antenna to said unit and having its conductors connected to opposite terminals of a first coil coupled to said loop antenna for voltage stepdown from the loop to said first coil and having its conductors connected to a second coil coupled to said coil in the input circuit, for the transfer of signals received in said loop antenna to said input circuit.

4. In combination, a radio receiving unit, a plurality of input circuits tunable to the frequency of signals in any one of a plurality of bands, each of said input circuits including a coil, means for tuning said coil to a frequency desirable for operation of said radio unit, a loop antenna arranged to be mounted remotely from said unit, means proximate to said loop for tuning it to a predetermined resonant frequency equal to the first mentioned frequency and corresponding to a frequency in any one of said plurality of bands, a low impedance untuned link circuit coupling said loop antenna to said coil of each of said input circuits, said link circuit comprising: a two-conductor cable extending from said loop antenna to said unit and having its conductors connected to opposite terminals of a first coil near said loop antenna for voltage stepdown between said loop antenna and said first coil and having its terminals connected to opposite terminals of a second coil coupled to said coil in each of said input circuits, for the transfer of energy from said loop antenna to said input circuit, and means for selectively connecting one of said tunable input circuits to said unit for the transfer of signals from said loop over said link circuit to said unit.

5. In combination, a radio receiver having an input circuit, a short wave loop antenna arranged to be mounted remotely from said unit, a base structure carrying said loop, variable capacitance means proximate to said loop for tuning it to any selected one of a group of predetermined resonant frequencies, an untuned coil mounted on said base and coupled to said loop for substantial voltage stepdown from said loop to said untuned coil, means comprising a low impedance network for transferring a voltage induced in said coil to the input circuit of said receiver, and means for tuning said input circuit to the said predetermined resonant frequencies, said coil having such a number of turns so that it serves to produce such substantial voltage stepdown and serves to match the impedance of the resulting tuned loop antenna with the impedance of such transferring means.

6. In combination, a receiver having an input circuit, a short wave loop antenna comprising a loop, a base structure carrying said loop, mounting means for said base whereby the loop may be located in desired positions, hinge means connecting said base to said mounting means whereby said loop may be oriented for best reception, variable capacitance means proximate to said loop whereby it may be tuned to a predetermined resonant frequency, a coil coupled to said loop and mounted on said base, means for transferring a voltage induced in said coil from said loop to the input circuit of said receiver, and means for tuning said input circuit to the same frequency as said predetermined resonant frequency.

7. In combination, a radio receiver having an input circuit, a short wave antenna comprising a loop, a base structure arranged to be placed remotely from said receiver and carrying said loop, a plurality of capacitors carried by said base, switching means for cutting individual capacitors into circuit with said loop whereby the same is tuned to any one of a plurality of predetermined resonant frequencies, a low impedance coil coupled to said loop for substantial voltage stepdown from said loop to said coil, said coil being mounted on said base, means for transferring a voltage induced in said coil from said loop to the input circuit of said receiver, and means for tuning said input circuit to the same frequency as said predetermined frequencies.

8. In combination, a portable radio receiver unit having an input circuit, means for tuning said input circuit to a frequency desirable for operation of said radio unit, a short wave loop antenna arranged to be mounted remotely relative to said unit, variable capacitance means arranged to tune said loop to a predetermined resonant frequency in a band of frequencies, and an untuned low impedance link circuit coupled to said loop and coupled to said input circuit of the unit for the transfer of radio energy selectively received in said loop to said unit.

9. In combination, a radio receiver having an input circuit, means for tuning said input circuit to a frequency desirable for operation of said receiver, a loop antenna arranged to be mounted in remote relation thereto, an untuned low impedance link circuit coupled to said antenna for substantial voltage stepdown from said loop to said link circuit, said link circuit being coupled to said input circuit and extending between said loop and radio receiver to communicate signals from said antenna to said receiver, and means proximate to said loop antenna for changing its resonant frequency to the first mentioned frequency.

10. In combination, a radio receiver having an input circuit, a pair of loop antennas, mounting means whereby said antennas may be mounted in alignment with a suitable dielectric surface, means pivotally connecting said loop antennas to said mounting means whereby said loop antennas may be oriented in the most advantageous direction for signal reception, tuning means proximate to one of said loop antennas whereby the same is adapted for the reception of a plurality of bands, a first coil coupled to said one loop antenna for substantial voltage stepdown from said last one loop antenna to said first coil, a second coil coupled to said input circuit, a pair of conductors extending between and connecting said first and second coils, said first coil and second coil and conductors comprising a link circuit, conductors connecting the other loop antenna to the input circuit of the receiver, cable means including all of said conductors, and switching means on the receiver for rendering each of said loop antennas alternatively effective to transfer signals to said receiver.

11. In combination, a radio receiver having an input circuit, a pair of loop antennas, mounting means whereby said antennas may be mounted in alignment with a suitable dielectric surface, means pivotally connecting said loop antennas to said mounting means whereby said loop antennas may be oriented in the most advantageous direction for signal reception, tuning means proximate to one of said loop antennas whereby the same is adapted for the reception of a plurality of broadcast bands, a first coil coupled to said one loop antenna for substantial voltage stepdown from said one antenna to said coil, a second coil coupled to said input circuit, a pair of conductors extending between and connecting said first and second coils in a series circuit, said series circuit comprising an untuned low impedance link circuit, conductors between the other loop antenna and input circuit of the receiver, cable means including said first and last mentioned conductors, switching means on the receiver for rendering each of said loop antennas alternatively effective

to transfer signal energy to said receiver, said switching means including band selecting means for adapting the receiver for the reception of signals in any of a plurality of said bands.

12. In combination, a radio receiver having an input circuit and a housing, a pair of loop antennas, mounting means whereby said antennas may be mounted in alignment with a suitable dielectric surface, means pivotally connecting said loop antennas to said mounting means whereby said loop antennas may be oriented in the most advantageous direction for signal reception, tuning means proximate to one of said loop antennas for tuning it at a predetermined resonant frequency for the reception of signals in a plurality of bands, a first coil coupled to said one loop antenna for substantial voltage stepdown, a second coil coupled to said input circuit, conductors extending between and connecting said first and second coils in a series circuit, said first coil, second coil and conductors forming an untuned low impedance link circuit, at least one additional conductor extending between and connecting the other loop antenna to the input circuit of the receiver, cable means including all of said conductors and extending from said loop antennas to the receiver, a telescopic antenna, said telescopic antenna being of such size with respect to said housing and arranged so that said antenna may be moved from a position substantially within said housing to a position where said antenna extends substantially entirely outside of said housing, switching means for alternatively connecting said other loop antenna and said telescopic antenna to said input circuit, an operating member for said switching means positioned in the path of movement of said telescopic antenna such that movement of said telescopic antenna between said position substantially within said housing and said position substantially outside of said housing results in alternatively connecting said other loop and said telescopic antenna to said input circuit, and switching means on the receiver for rendering each of said loop antennas alternatively effective to transfer signals therefrom to said input circuit.

13. In combination with an antenna for the reception of radiated energy, a receiver arranged to be energized by such energy and located at a substantial distance from said antenna, a tuned input circuit for the receiver, said antenna being tuned to the same frequency as said input circuit a low impedance link circuit extending between said antenna and receiver and including means at its ends for coupling said antenna to said link circuit and for coupling said link circuit to said input circuit of the receiver, said coupling means comprising means for reducing the voltage of said energy passing from said antenna to said link circuit and for increasing the voltage of said energy passing from said link circuit to the input circuit of said receiver.

14. In combination, radio apparatus, a housing for the radio apparatus, said radio apparatus including metal parts, a first antenna, a second antenna, means within said housing for movably mounting said first antenna with respect to said housing, said first antenna being of such size with respect to said housing and arranged so that said first antenna may be moved from a position substantially within said housing wherein said metal parts impair the effectiveness of said first antenna to a position substantially entirely outside of said housing wherein said metal parts influence in small degree the effectiveness of said first antenna, and switching means for rendering said first antenna and said second antenna alternatively effective for the passage of signals between said antennas and said apparatus, said switching means including a member arranged to move with said first antenna during at least a portion of the movement of said first antenna between said position within said housing and said position outside of said housing, said member being arranged to disconnect said second antenna from said apparatus and to connect said first antenna to said apparatus in response to movement of said first antenna to said outside position, the resulting connections being reversed upon movement of said first antenna to said position within said housing.

15. In combination, radio apparatus including an energy transferring circuit, a houisng for said apparatus, said radio apparatus including metal parts, an antenna movable from a position within said housing wherein said metal parts impair the effectiveness of said antenna to a position substantially outside of said housing wherein said metal parts influence in small degree the effectiveness of said antenna, and means including an operating member positioned in the path of movement of said antenna operated in response to movement of said antenna from said position within said housing to a position outside of said housing for electrically connecting said antenna to said circuit for the transfer of radio energy between said radio apparatus and antenna.

16. In combination, a radio apparatus, a housing for said radio apparatus, said radio apparatus including metal parts, a first antenna, a second antenna, means for movably mounting said first antenna with respect to said housing, said first antenna being of such size with respect to said housing and arranged so that said first antenna may be moved from a first position substantially within said housing wherein said metal parts impair the effectiveness of said first antenna to a second position substantially entirely outside of said housing wherein said metal parts influence in small degree the effectiveness of said first antenna, and means including an operating member positioned in the path of movement of said first antenna operated in response to movement of said first antenna between said position within said housing to said position substantially entirely outside of said housing for alternatively connecting electrically said antennas to said apparatus for the passage of signals therebetween.

17. In combination, radio apparatus including a radio energy transferring circuit, said apparatus including metal parts, a first antenna movable from a position relatively near said apparatus wherein the effectiveness of said antenna is impaired by said metal parts to a position more remote from said apparatus wherein said metal parts influence in small degree the effectiveness of said antenna, a second antenna, and means responsive to movement of said first antenna from said position relatively near said apparatus to said more remote position for electrically disconnecting said second antenna from said energy transferring circuit and for electrically connecting said first antenna to said energy transferring circuit for the transfer of radio energy between said radio apparatus and first antenna, said disconnecting and connecting means including a member arranged to move with said first an-

tenna during at least a portion of the movement of said first antenna between said positions, said member being arranged to move to open a circuit between said second antenna and said energy transferring circuit in response to said movement and to close a circuit between said first antenna and said energy transferring circuit in response to said movement.

18. In combination, a radio receiver having a housing, said receiver including metal parts, a telescopic rod antenna mounted on said receiver for transferring signals thereto and arranged to extend substantially within said housing when the antenna is telescoped wherein said metal parts impair the effectiveness of said antenna and to extend substantially outside of said housing when the antenna is extended in which position said metal parts influence in small degree the effectiveness of said antenna, a second antenna for transferring signals to the receiver, switching means including an operating member positioned in the path of telescoping movement of the first mentioned antenna operated in response to movement of said first mentioned antenna from its telescoped position within said housing to its extended position outside of said housing for rendering said first mentioned and second antennas alternatively effective for the passage of signals between said antennas and receiver.

19. In combination, a radio receiver, said receiver including metal parts, a telescopic antenna mounted on said receiver for transferring signals thereto and arranged to be positioned in close proximity to said receiver when the antenna is telescoped in which position said metal parts impair the effectiveness of said antenna and to extend a substantial distance away from the receiver when the antenna is extended in which position said metal parts influence in small degree the effectiveness of said antenna, a loop antenna for transferring signals to the receiver, and switching means for rendering said first and second antennas alternatively effective for the passage of signals between the antennas and receiver, said switching means including a member arranged to move with said first mentioned antenna during at least a portion of the movement of the first mentioned antenna from its position close to said receiver to its position a substantial distance from said receiver, said member being arranged to move to disconnect said loop antenna from said receiver and to connect said first mentioned antenna to said receiver in response to said movement.

20. In combination, radio apparatus, a housing for said apparatus, said apparatus including metal parts, an antenna, means within said housing for movably mounting said antenna with respect to said housing, said antenna being of such size with respect to said housing and arranged so that said antenna may be moved from a position substantially within said housing wherein said metal parts impair the effectiveness of said antenna to a position where said antenna extends substantially entirely outside of said housing wherein said metal parts influence in small degree the effectiveness of said antenna, and means including an operating member positioned in the path of movement of said antenna responsive to movement of said antenna from said position substantially within said housing to said position entirely outside of said housing for operatively connecting electrically said antenna to said apparatus for the passage of signals therebetween.

21. In combination, radio apparatus, a housing for said radio apparatus, said apparatus including metal parts, an antenna movable from a position within said housing wherein said metal parts impair the effectiveness of said antenna to a position outside of said housing wherein said metal parts influence in small degree the effectiveness of said antenna, and means including an operating member positioned in the path of movement of said antenna responsive to movement of said antenna from said position within said housing to said position outside of said housing for electrically connecting said antenna to the apparatus for the passage of signals therebetween.

22. In combination, radio apparatus, a housing for said apparatus, a telescopic rod antenna for the reception of signals and movable from a telescoped position within said housing in close proximity to said apparatus to an extended position outside of said housing removed from said apparatus, said apparatus having metal parts which materially influence a function of the antenna when said antenna is positioned within said housing and in proximity to said apparatus, and means for connecting electrically said antenna to the apparatus for the passage of signals therebetween, said connecting means including a member arranged to move with said antenna during at least a portion of the movement of said antenna between its telescoped and extended positions, said member being arranged to move to close a circuit between said antenna and said apparatus in response to said movement.

23. In combination, radio apparatus normally disposed near the earth's surface, a rod antenna attached mechanically to said apparatus and movable from a vertical position with respect to the earth's surface where said antenna is highly effective to pass signals to a position where said rod antenna extends substantially parallel to the earth's surface, and means for operatively connecting electrically said antenna to said apparatus for the passage of signals therebetween, said connecting means including a member arranged to move with said antenna during at least a portion of the movement of said antenna from said horizontal position to said vertical position, said member being arranged to move to close a circuit between said antenna and said apparatus in response to said movement.

24. In combination, radio apparatus including a radio energy transferring circuit, a first antenna movable with respect to said apparatus, a second antenna, and switching means for alternately connecting said first antenna and second antenna electrically with said radio energy transferring circuit for the alternate transfer of radio energy between said antennas and said apparatus, said switching means including a member arranged to move with said first antenna during at least a portion of the movement of said first antenna with respect to said apparatus, said member being arranged to move to connect said circuit to one of said antenna and disconnect said circuit from the other antenna in response to said movement.

25. In combination, means for receiving radio frequency energy, said means having a high impedance input circuit, a loop antenna winding spaced a substantial distance from said input circuit, a low impedance untuned link circuit extending between said input circuit and antenna winding and arranged to transfer radio frequency energy therebetween, said link circuit including a

coil, means mounting said antenna winding and link circuit coil in close proximity to each other such that said antenna winding and link circuit coil comprise elements of a transformer, means for tuning said antenna winding to a frequency of signals desirable for operation of said radio receiving means, means for tuning said input circuit to the same frequency at which said antenna winding is tuned, and means for matching the impedance of the resulting tuned antenna winding to the low impedance of said link circuit, and means for matching the high impedance of said input circuit in said radio receiving means to the low impedance of said link circuit whereby radio energy is efficiently transferred between said antenna winding and link circuit and input circuit and variations of stray capacity of such link circuit produce no substantial effect on the transfer of such radio energy.

26. In combination, a radio receiver having an input circuit, a pair of loop antennas for the reception of radio signals, said antennas being arranged to be mounted remotely relative to the receiver, tuning means proximate to one of said antennas for tuning it to a predetermined resonant frequency, means for tuning said input circuit to a frequency equal to said predetermined frequency, means including conductors for coupling said one antenna to the input circuit of said receiver, means including at least one other conductor for coupling the other antenna to the input circuit of said receiver, flexible cable means including said conductors extending between said antennas and receiver, switching means on the receiver for rendering alternatively effective said one and the other antenna to transfer signals therefrom to said input circuit, said switching means including band selecting means for adapting the receiver for the reception of signals in any of a plurality of broadcast bands.

27. In combination, means for translating radio frequency energy, said means having an energy transferring circuit, a loop antenna spaced a substantial distance from said energy transferring circuit, means for tuning said antenna to a frequency desirable for the transmission of energy to said translating means, a low impedance untuned link circuit extending between said energy transferring circuit and said antenna and arranged to transfer radio frequency energy therebetween, means for tuning said transferring circuit to said desirable frequency, whereby radio energy is efficiently transferred between said antenna and link circuit and variations of stray capacity of said link circuit produce no substantial effect on transfer of such radio energy, a low capacity antenna arranged to be connected to said energy transferring circuit, and switching means for alternatively connecting said antennas to said energy transferring circuit for the transfer of energy therebetween.

28. In combination, means for translating radio frequency energy, said means having an energy transferring circuit, a loop antenna spaced a substantial distance from said energy transferring circuit, means proximate to said antenna for tuning it to predetermined frequencies, a low impedance untuned link circuit extending between said energy transferring circuit and said antenna and arranged to transfer radio frequency energy therebetween, means for tuning said transferring circuit to frequencies equal to said predetermined frequencies, whereby radio energy is effectively transferred between said antenna and link circuit and variations of stray capacity of said link circuit produce no substantial effect on transfer of such radio energy, a movable low capacity antenna arranged to be connected to said energy transferring circuit, and means responsive to movement of said last antenna for alternatively connecting said antennas to said energy transferring circuit for the transfer of energy therebetween.

29. In combination, a radio receiver having an input circuit, a pair of antennas operable for the reception of radio signals in different frequency bands and being arranged to be mounted remotely relative to the receiver, means proximate to one of said antennas for tuning it to predetermined frequencies, means for tuning said input circuit to frequencies equal to said predetermined frequencies, means for coupling said antennas to the input circuit for the transfer of radio frequency energy in different frequency bands to said input circuit, and means on the receiver for rendering each of said antennas alternatively effective to transfer radio frequency energy in different frequency bands to said receiver.

30. In combination, a radio receiver having an input circuit, a first and a second antenna operable for the reception of signals in different frequency bands, means proximate to said first antenna for tuning said first antenna to predetermined frequencies, said input circuit including a plurality of tuned circuits tunable to frequencies equal to said predetermined frequencies and arranged to be selectively coupled to said first antenna for the selective reception of signals in a plurality of frequency bands, switching means for selectively coupling one of said tuned circuits to said first antenna, means for coupling said second antenna to the input circuit of the receiver, and means responsive to operation of said switching means for uncoupling said first antenna from said input circuit.

31. In combination, a radio receiver having an input circuit, a first antenna and a second antenna arranged for the reception of radio signals in different frequency bands, means for coupling said first antenna to said input circuit for the transfer of radio energy therebetween, means for coupling said second antenna to said input circuit for the transfer of energy therebetween, said last mentioned means including one of a plurality of tuned circuits tuned to predetermined frequencies for the selective transfer of signals between said second antenna and input circuit in any one of a plurality of frequency bands, means for tuning said second antenna to frequencies equal to said predetermined frequencies, means for selectively connecting one of said plurality of tuned circuits in operative relationship for the selective transfer of signals between said second antenna and input circuit, and means responsive to actuation of said connecting means for uncoupling said first antenna from said input circuit.

32. In combination, an antenna, means proximate to said antenna for tuning the same to a single frequency within a range of frequencies, radio receiving apparatus, an input circuit for said radio receiving apparatus located remotely relative to said antenna, means for tuning said input circuit to a single frequency equal to the first mentioned frequency, and a low impedance circuit coupling the resulting tuned antenna to the resulting tuned input circuit, the overall coupling between the antenna and input circuit being of small degree such that efficient energy

transfer consistent with high selectivity and image ratio results.

33. In combination, a radio receiver, said receiver having a plurality of input circuits each tunable to the frequency of signals in a different range, means for connecting any selected one of said tunable input circuits to said receiver, means for tuning the selected circuit to any desired signal frequency within its range, a loop antenna arranged to be mounted remotely from said receiver, antenna tuning means proximate to the loop comprising discontinuous means for tuning the loop to any selected one of a plurality of frequencies each in a different one of said ranges and continuous means for tuning the loop to any signal frequency within the range for which the discontinuous means has been set, and means for coupling said antenna to the selected input circuit, said coupling means comprising a line having a coil at one end coupled to said loop antenna for substantial voltage stepdown from antenna to coil, means to match the impedance of said loop antenna to the impedance of the line, and means to match the line impedance to the impedance of the selected input circuit, said coupling means having a low characteristic impedance, a low shunt capacity, and providing a small degree of coupling between said antenna and input circuit.

34. In combination, radio receiving apparatus having an input circuit, means for adjustably tuning said input circuit, a loop antenna, means proximate to said antenna for adjustably tuning said antenna to a frequency corresponding to the frequency to which the input circuit is tuned, means for coupling said antenna to said input circuit, said coupling means comprising a long flexible line having a coil at one end coupled to said loop and arranged for substantial voltage stepdown from said loop to said coil, the overall coupling between said loop and said input circuit being of small degree, and means for quickly attachably and detachably supporting said antenna at a point removed from said receiving apparatus.

35. In combination, a radio receiver having an input circuit, means for adjustably tuning said input circuit to a frequency desirable for operation of said receiver, a loop antenna arranged to be mounted in remote relation thereto, a line having a low characteristic impedance and a low shunt capacity, means for coupling in small degree said antenna to said line for substantial voltage stepdown from said antenna to said line, and means for coupling in small degree said line to said input circuit, said line extending between said antenna and input circuit to communicate signals from said antenna to said input circuit, and means proximate to said loop antenna for tuning it to the first mentioned frequency.

36. In combination, a radio receiver, said receiver having a plurality of input circuits tunable to the frequency of signals in any one of a plurality of bands in a relatively large frequency spectrum, means for connecting any selected one of said tunable circuits to said receiver, means for tuning the selected circuit to any signal frequency within the selected band, a loop antenna arranged to be mounted remotely from said receiver, antenna tuning means proximate to this loop comprising discontinuous means for tuning the loop to any selected one of a plurality of frequencies each in a different one of said bands, and continuous means for tuning the loop to any signal frequency within the band corresponding to the frequency to which said input circuit is tuned, and means for coupling said antenna to the selected input circuit, said coupling means comprising a line having a coil at one end coupled to said loop antenna for substantial voltage stepdown from antenna to coil, said coupling means having a low characteristic impedance, a low shunt capacity, and a low overall coefficient of coupling.

37. In combination, a radio receiver, said receiver having a plurality of input circuits tunable to the frequency of signals in any one of a plurality of bands in a relatively large frequency spectrum, means for connecting any selected one of said tunable input circuits to said receiver, means for tuning the selected circuit to any signal frequency within the selected band, a loop antenna arranged to be mounted remotely from said receiver, antenna tuning means proximate to the loop comprising discontinuous means for tuning the loop to any selected one of a plurality of frequencies each in a different one of said bands and continuous means for tuning the loop to any signal frequency within the band corresponding to the frequency to which said input circuit is tuned, and means for coupling said antenna to the selected input circuit, said coupling means having a low characteristic impedance and a low shunt capacity and a low overall coefficient of coupling and comprising a line having a coil at one end coupled to said loop antenna, said coupling means being arranged to maintain the voltage therein substantially lower than the voltage in either said antenna or the selected input circuit, means to improve the impedance match between said antenna and said line and between said line and said input circuit, and means for quickly attachably and detachably supporting said antenna at a point removed from said receiver.

38. In combination, a radio receiver having an input circuit, means for tuning said input circuit to any desired frequency within a range of frequencies, a first antenna, means proximate to said antenna for tuning it to the same frequency as said input circuit, said first antenna being movable to a position removed from said input circuit, means for coupling said antenna to said input circuit, said coupling means having a low characteristic impedance and being arranged to provide overall coupling between said antenna and said input circuit of such small degree that efficient energy transfer consistent with high selectivity results, a second antenna, and means for connecting said second antenna with said input circuit and disconnecting said coupling means therefrom and alternatively for disconnecting said second antenna from said input circuit and connecting said coupling means thereto.

39. In combination, radio receiving apparatus having an input circuit, means for adjustably tuning said input circuit to any desired frequency within the short wave range, a loop antenna, means proximate to said antenna for adjustably tuning said antenna to a frequency corresponding to said desired frequency, and long flexible means for coupling said antenna to said input circuit, the overall coefficient of coupling between said antenna and said input circuit lying in a range of medium to loose coupling, said coupling means having a low characteristic impedance and a low shunt capacity.

40. In combination, a radio receiver having an input circuit, means for tuning said input circuit to any desired frequency within a range of frequencies, a first antenna, means proximate to

said antenna for tuning it to the same frequency as said input circuit, said first antenna being movable to a position removed from said input circuit, means for coupling said antenna to said input circuit, said coupling means having a low characteristic impedance and being arranged to provide overall coupling between said antenna and said input circuit of such small degree that efficient energy transfer consistent with high selectivity results, a second antenna, and means responsive to movement of one of said antennas with respect to said receiver for connecting said second antenna with said input circuit and disconnecting said coupling means therefrom and alternatively for disconnecting said second antenna from said input circuit and connecting said coupling means thereto.

41. In combination, an antenna, means proximate to said antenna for adjustably tuning the antenna to any desired frequency, radio receiving apparatus, an input circuit for said radio receiving apparatus, means for adjustably tuning said input circuit to a frequency equal to said desired frequency, and a flexible line having a low characteristic impedance and a low shunt capacity for coupling said antenna to said input circuit, the overall coupling between said antenna and input circuit being of small degree, means for supporting said antenna and said line on said receiving apparatus, said line being of sufficient length that when coupled between said antenna and input circuit, the antenna may be located at a remote point with respect to the input circuit, and means for quickly attachably and detachably supporting said antenna at such a remote point.

42. In combination, means for receiving radio frequency energy, said means having a high impedance input circuit, a loop antenna winding arranged to be placed a substantial distance from said energy receiving means, a line having a low characteristic impedance and a low shunt capacity extending between said energy receiving means and antenna winding and arranged to transfer energy therebetween, said line including a coil, means mounting said antenna winding and coil in close proximity to each other such that said antenna winding and coil comprise elements of a transformer, means variable to tune said antenna winding to a frequency of signals desirable for operation of said receiving means, means variable to tune said energy receiving means to the same frequency as the antenna winding is tuned, means for matching the high impedance of the tuned antenna winding to the low impedance of said line, and means for matching the high impedance of said energy receiving means to the low impedance of said line, said line being coupled to said antenna and said receiving means in small degree.

43. In combination, a radio receiver, said receiver having a plurality of input circuits tunable to the frequency of signals in any one of a plurality of bands in a relatively large frequency spectrum, means for connecting any selected one of said tunable input circuits to said receiver, means for tuning the selected circuit to any signal frequency within the selected band, a loop antenna arranged to be mounted remotely from said receiver, antenna tuning means proximate to the loop comprising discontinuous means for tuning the loop to any selected one of a plurality of frequencies each in a different one of said bands and continuous means for tuning the loop to any signal frequency within the band corresponding to the frequency to which said input circuit is tuned, and means for coupling said antenna to the selected input circuit, said coupling means having a low characteristic impedance, a low shunt capacity, and a low overall coefficient of coupling.

POWERING ELECTRICAL DEVICES WITH ENERGY ABSTRACTED FROM THE ATMOSPHERE

Lloyd R. Crump, Silver Spring, Md.

Application March 12, 1954, Serial No. 415,986

1 Claim. (Cl. 321—2)

(Granted under Title 35, U. S. Code (1952), sec. 266)

The invention described herein may be manufactured and used by or for the Government for governmental purposes without payment to me of any royalty thereon.

This invention relates to the convenient and economical provision of power for the operation of electronic circuits and devices using transistors, and of other electrical devices having modest power requirements.

A great advantage of transistors, and a major reason for their enthusiastic reception since their introduction a few years ago, is the fact that they will operate satisfactorily with very low supply voltages and currents. One milliwatt or even less is sufficient to power a transistor in many applications. Various batteries have been developed to provide, in a minimum of space, the relatively minute amounts of power needed by transistors.

My invention provides methods and means that permit transistor circuits, and also other low-powered electrical devices, to be economically and conveniently operated without any batteries whatever, and indeed without any power supply whatever as power supplies are ordinarily conceived.

The invention centers around my discovery that it is practicable to construct operative transistor circuits that are able to abstract from the atmosphere sufficient electromagnetic energy to provide all necessary supply voltages and currents for their own operation. Circuits and devices powered according to my invention will operate indefinitely without any local power source whatever.

I have successfully constructed and demonstrated such circuits. For example, I have constructed a batteryless transistor radio receiver on which I have listened to either nearby or distant broadcast stations as desired, using either headphones or a loudspeaker; this receiver has been powered entirely by electromagnetic energy abstracted from the atmosphere.

From the successful operation of this receiver, and from other experimental work, it becomes clear that, by the methods and means of the invention, a great variety of practical and useful transistor circuits can be powered entirely by energy abstracted from the atmosphere.

Furthermore, as will become apparent below, my invention is applicable to the powering of other electrical devices requiring relatively small amounts of power.

An object of the present invention is to provide methods and means for powering transistor circuits entirely from radiofrequency energy abstracted from the atmosphere.

Another object is to provide methods and means for powering remote radio receivers, low-powered radio transmitters, and other low-powered electrical devices, with energy received by radio from a master station, so that no local power supplies are needed by the devices and so that the powering or non-powering of the remote device is under the control of the master station.

A further object is to provide methods and means for powering transistor circuits and other low-powered electrical devices with radiofrequency energy received from one or more remote radio transmitters.

Other objects, aspects, uses, and advantages of the invention will become apparent from the following description and from the drawing.

Figure 1 is a schematic diagram of a transistor radio receiver in which all necessary power is supplied by energy abstracted from the atmosphere in accordance with the invention.

Figure 2 is a schematic diagram showing a general application of the invention to provide direct-current power to a load.

Figure 3 is a schematic diagram of a system for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere.

Referring to Figure 1, a receiving antenna **1** is connected to antenna coupling coils **2** and **3**, the other ends of which are connected to ground. A parallel resonant circuit consisting of coil **5** and capacitor **6** is coupled to coil **2**. A second parallel resonant circuit consisting of coil **7** and capacitor **10** is coupled to coil **3**. A third parallel resonant circuit consisting of coil **11** and capacitor **12** is also coupled to coil **3**.

Coil **5** and capacitor **6** are tuned to the frequency of a radio transmitter from which it is desired to receive information—for instance, an amplitude-modulated standard broadcast station. The signal received from this transmitter need not be strong. The signal is detected by diode **15** to obtain an audio-frequency information signal. This audio signal is coupled through a capacitor **16** and is amplified by a circuit that includes a transistor **17** having a base **20**, an emitter **21**, and a collector **22**. The amplified audio output of the transistor is coupled through an audio transformer **23** to an electroacoustical transducer, preferably a permanent-magnet dynamic loudspeaker **25** as shown.

The novelty of the invention lies largely in the method and means by which the necessary direct-current power is supplied to the emitter and collector circuits of transistor **17**. This method and means will now be described.

Coil **7** and capacitor **10**, and also coil **11** and capacitor **12**, are tuned to receive radio signals of relatively high strength. It does not matter whether these signals contain information. These power signals are rectified by diodes **26** and **27** to provide direct-current power that is filtered by capacitors **30** and **31**. The D.-C. power thus obtained is utilized to power the transistor **17**.

In the circuit shown, two tuned circuits (coil **7** and capacitor **10**, and coil **11** and capacitor **12**) are tuned to power signals and the D.-C. voltages obtained from each are connected in series. The tuned power circuits may be tuned to the same or different power signals. Under certain circumstances it may be desirable to use more than two tuned power circuits and to tune them to more than two power signals; in this way power can be obtained from several signals and combined. On the other hand, if a strong power signal is available, a single tuned power circuit may suffice to give the needed D.-C. power.

Even weak information signals can be received successfully. A plurality of transistor amplifier stages can be used if desired, or other circuits such as superheterodyne circuits can be used. It is merely necessary that a sufficiently strong power signal or signals be available to provide the small amount of D.-C. needed to power the transistors.

If the information signal happens to be strong, it can be used as the power signal; all of the tuned circuits (coil **5** and capacitor **6**, coil **7** and capacitor **10**, coil **11** and capacitor **12**) are tuned to the information signal.

Engineers who have observed my invention in operation have been surprised at the unexpectedly good results obtained, even with readily available power signals of quite moderate strength. For instance, sufficient power for satisfactory operation of a loudspeaker at low volumes is

readily obtained from a 5-kilowatt standard broadcast station 5 miles away, using only an indoor antenna to pick up the power signal as well as information signals. In typical operation under these conditions a D.-C. voltage of about 2.5 to 3 volts is obtained between the emitter and the collector, at a current of about 250 microamperes; D.-C. power input to the transistor is thus of the order of 0.5 to 1 milliwatt. So far as I am aware, no one has ever before discovered and demonstrated the practicability of this method of powering a radio receiver.

Because existing broadcast stations within a radius of a number of miles provide adequate power signals, the invention is readily practicable with existing power signals in almost any location in or near any city in the United States.

Although I have described a transistor radio receiver powered by my invention, it will be readily apparent that the invention is applicable to the powering of any transistor circuit using one or a number of transistors, and to the powering of other devices requiring relatively small amounts of power. For instance, sensitive electromechanical, electrochemical, or electrothermal devices can be operated by the method of the invention.

Referring to Figure 2, which shows a more general embodiment of my invention, an antenna **35** picks up radiofrequency energy from the atmosphere. This energy flows through coil **36**, which is coupled to a tuned circuit consisting of coil **37** and capacitor **40**. The radiofrequency voltage across capacitor **40** is rectified by diode **41** and filtered by a low-pass filter **46** consisting of capacitors **42** and **44** and choke coil **43**. The resulting D.-C. voltage is applied to a load **45**.

In the practice of my invention, larger amounts of power can be obtained for short periods of time by storing received energy in a suitable energy storage device. Stored energy may then be withdrawn at intervals at a more rapid rate than that at which it was received and put into the storage device. In this way the invention can be used to provide short pulses of relatively very high electrical energy. This result can be readily obtained by charging a relatively large capacitor with direct current and then discharging the capacitor rapidly into a load when desired. This rapid discharge can be initiated automatically when the voltage across the capacitor reaches a certain level, or it can be initiated when a transistor radio receiver receives a certain information signal.

Higher voltages can be obtained with the invention by means of well known devices for raising D.-C. voltages as shown in Figure 3. The D.-C. voltage output from the capacitor **44** can be used to power a low frequency transistor oscillator **52** whose A.-C. output is raised to a higher voltage level by the transformer **55**. This relatively high A.-C. voltage can then be rectified by a diode **61** and fed to a capacitor **64** to provide a high energy D.-C. source at a relatively high voltage level at the terminals **69** and **70**. If desired, energy can now be withdrawn from the capacitor **64** at intervals in short pulses of high energy at a high voltage level. Pulsed radio transmission is one of the possible uses for this form of the invention. Other uses would be to provide a single relatively powerful pulse needed to actuate an electrothermal or electromechanical device.

As has been indicated above, in many locations and particularly anywhere in or near most American cities, power signals normally present in the atmosphere are readily available for the easy and convenient practice of the invention. However, the invention also has important applications in systems in which the necessary power signal is generated and transmitted specifically for the operation of the particular system. Such systems can, for example, comprise a master station transmitting all the power that is needed for hundreds or thousands of fixed or mobile transistor receivers or other remote devices over a range of many miles. This eliminates the need for hundreds or thousands, as the case may be, of local power supplies. At the same time, such a system has the advantage that all of the remote devices can be simultaneously activated or deactivated at the will of the master station, simply by starting or stopping the transmission of the power signal. In such systems it will often be advantageous to use power signals of frequencies sufficiently high to permit the use of resonant receiving antennas of small physical dimensions for signal pickup at the remote devices. In addition to the power signal, the master station may transmit an information signal on the same or a different carrier.

Certain types of devices powered entirely by received radio waves are of course well known. The well-known "crystal set" of the early days of radio, which used a diode rectifier to demodulate an amplitude-modulated radiofrequency signal, is an outstanding example of such a device. My invention is readily distinguishable from such prior devices, however. In typical prior devices a modulated radiofrequency signal is applied to a diode to obtain unidirectional half-wave pulses whose amplitudes vary with modulation. These pulses are integrated by means of a capacitor to obtain a unidirectional signal the amplitude of which follows the audiofrequency modulation envelope. If the radiofrequency signal is received with sufficient strength the audio signal may have sufficient power to operate headphones or similar utilization device without power amplification; but the signal is utilized for its information content, rather than to supply non-information-containing power.

My invention, on the other hand, entails the utilization of received radiofrequency energy to supply power to at least one pair of circuit points (across capacitor **31** in Fig. 1, for example), such circuit points requiring power solely for its power content and not for any information or modulation it may contain. In other words, my invention entails the utilization of radiofrequency energy to supply power that would otherwise have to be supplied by batteries, generator, or other local power source.

It will be apparent that the embodiments shown are only exemplary and that various modifications can be made in construction and arrangement within the scope of the invention as defined in the appended claim.

I claim:

An electrical device for obtaining a high energy D.-C. source at a high voltage level using energy abstracted from the atmosphere, said device comprising in combination: resonant means for receiving radio waves, first rectifier means for converting said radio waves into first direct current energy, first capacitor means for storing said first direct current energy, an oscillator powered by said direct current energy, said oscillator producing an A.-C. output, transformer means for raising said A.-C. output to an increased voltage level, second rectifier means for converting the A.-C. output of increased voltage level from said transformer into second direct current energy, and second capacitor means for storing said second direct current energy.

ABSTRACT OF THE DISCLOSURE

A combined antenna and conversion mechanism for reception of beamed high frequency electromagnetic energy in space including a large array of unidirectional current semiconductor rectifier devices. A self-supporting space vehicle utilizing the rectified DC electrical energy for propulsion is disclosed in an illustrative embodiment.

The present invention relates in general to the transfer of energy by means of an electromagnetic wave beam and more particularly to interception and rectification of such energy into low frequency electrical DC energy with a high degree of efficiency.

Improved technology in the field of microwave energy generation at superpower levels has resulted in the realization of electrical energy transmission over considerable distances for remote energization of devices or vehicles without the aid of wires. The transmission of microwave electromagnetic energy into space has been commonly employed in the radar pulse echo systems for the detection and orientation of desired objects within a predetermined scanning range of a transmitting antenna. Beams of a similar nature may now be employed for other useful purposes and the advantages attendant the utilization of electromagnetic energy in the microwave region in contrast with other wavelengths may now be enumerated.

Microwaves have been generally defined as high frequency radio waves whose wavelength is less than 30 centimeters, with a lower wavelength limit on the order of 1 millimeter sometimes being applied to what is commonly referred to as the "microwave region." The superiority of high frequency microwaves is due in part to the fact that it is generally desirable to focus the transmitted energy so as to achieve a high power density at a remote point or area with respect to a given power source. In accordance with the laws of optics, the sharpness of the microwave beam produced by a transmitting antenna varies as the ratio of antenna dimensions to the wavelength of the transmitted energy. Therefore, for a given or desired power density or beam sharpness, a decrease in the wavelength of the transmitted energy permits a corresponding decrease in the dimensions of the antenna. From the standpoint of mechanical considerations, it is desirable to employ small antennas and other components, and it is therefore advantageous to employ high frequency energy of very short wavelength. In addition, the difficulties encountered in long wave transmission as a result of natural and man-made interference or noise do not occur with any appreciable significance at microwave frequencies. Further, in aerospace applications with considerable distances separating the transmitter at an earth or mother planet location and the employment of shorter wavelength beamed energy is preferred since longer wave signals will generallly be reflected at certain altitudes by reflecting layers in the atmosphere.

In view of certain losses due to absorption which may occur in the atmosphere, microwaves in the region having the approximate bounds of 2 and 30 centimeters are readily adaptable to the convenient radiation of power to remote points without the utilization of wires. The preferred wavelengths are of the order of 5 or 10 centimeters to provide efficient focusing with existing transmitting antenna systems which may be maintained at a reasonable size. An illustrative device of the superpower high frequency microwave generators operative in the desired band is the so-called Amplitron which is an amplifier having a broad bandwidth and excellent performance characteristics for the focusing of the beam. Such devices are capable of producing 15 or 20 kilowatts of average continuous wave power in the neighborhood of 10 centimeters in wavelength with capabilities expected in the region of 500 kilowatts or more average power with 50 megawatts peak power. A complete description of such devices may be had by referring to Patent No. 2,933,723 issued Apr. 19, 1960 to William C. Brown and assigned to the assignee of the present invention.

With microwave energy capable of being generated and directed over longer distances conversion of such high frequency electromagnetic energy is of paramount concern. One conversion mechanism in the prior art involves direct conversion of such energy into heat which may then be utilized directly or indirectly for propulsion or generation of flight-producing forces. Examples of such devices for heat energy exchange as well as space vehicles utilizing such energy may be noted in Patent No. 3,174,-705, issued Mar. 23, 1965, to D. Schiff et al., as well as U.S. Letters Patent No. 3,083,528, issued Apr. 2, 1963 and No. 3,114,517, issued Dec. 17, 1963, to William C. Brown. The heat exchanger method of conversion of electromagnetic energy into useful power is limited by the overall efficiencies of approximately 25 percent in the conversion of heat into mechanical or electrical work. Desirable, therefore, would be the direct rectification of the high frequency electromagnetic energy into low frequency electrical energy for the operation of many useful aerospace devices as well as systems.

The present invention has for its primary object the conversion of high frequency electromagnetic energy in the microwave region directly into low frequency electrical energy.

A further object of the present invention is the provision of a combined nondirectional receiving antenna and microwave electromagnetic energy to low frequency electrical energy conversion means in a unitary structure.

A still further object of the present invention is a provision of a new and novel combined nondirectional receiving antenna and microwave to DC energy converter for aerospace applications.

Another object of the present invention is the provision of a new and novel nondirectional receiving antenna and microwave to DC energy converter having a high degree of efficiency.

Still another object of the present invention is the provision of a new and novel aerospace vehicle with nondirectional receiving antenna and microwave to DC energy converter means with said vehicle being capable of being supported by its own energy generation means at a distance spaced apart from the power generation means.

In accordance with the teachings of the present invention, the above and other objects are achieved by the employment of efficient unidirectional microwave power rectifiers and dipole antenna means. Such rectifying devices, while being individually limited in power-handling capabilities, normally in the order of fractions of watts, have been found to be highly efficient means for the rectification of microwave power when assembled in large numbers in various arrays. It is interesting to note that the observed collective efficiency was on the order of 40 to 70 percent. In an illustrative embodiment, point-

contact semiconductor diodes were arranged in four arm bridge connected networks with the networks interconnected in various configurations such as series, parallel and series-parallel.

In discussing aerospace applications, an additional problem is encountered in the beaming of microwave energy to a remote point and the interception and utilization of such electrical energy. In such applications the advantages of a vehicle which may be maintained in space for indeterminate periods of time without employing a local fuel source are readily apparent. Such devices could readily provide communication networks, surveillance functions using radar techniques along with numerous other functions. The acapture of the beamed high frequency electromagnetic energy raises the need for an efficient antenna means capable of intersecting the beam at high altitudes. Conventional techniques employed in microwave radar usage such as receiving antenna horns are capable of intersecting only a small portion of the beam energy and add considerable weight in applications involving heavier-than-air vehicles. In an exemplary embodiment of the invention a space vehicle, namely a helicopter, is disclosed for either moving flight or a stationary location with self-supporting electrically operative propulsion means. The semi-conductor diode rectifier arrays have been demonstrated to fulfill the receiving antenna functions as well as the electrical energy rectification means in a highly efficient manner. Such combined antenna and rectifier means has also assisted in reduction of the weight problem in airborne devices. Further, it has provided a nondirectional means for the interception of the microwave energy to thereby reduce the problems of focusing inherent in prior art directional horn type receiving antennas.

With the above features, advantages and objects in mind the invention will now be described by reference to the following detailed description together with the accompanying drawings in which:

FIG. 1 is a perspective view of an illustrative diode rectifier;

FIG. 2 is a schematic circuit diagram of a bridge connected diode network with dipole antenna means;

FIG. 3 is a schematic circuit diagram of a plurality of bridge connected networks arranged in series;

FIG. 4 is a schematic circuit diagram of a parallel bridge connected network array;

FIG. 5 is a perspective view of an illustrative embodiment of a combined antenna and rectifier array in a folded or rolled up configuration;

FIG. 6 is a schematic circuit diagram illustrating the bridge connected diode array incorporated in the aerospace vehicle shown in FIG. 7;

FIG. 7 is a schematic representation in elevation illustrative of a heavier-than-air aerospace vehicle incorparating the structure of the present invention;

FIG. 8 is a perspective view of the aerospace vehicle embodiment as viewed from the under portion thereof; and

FIG. 9 is an enlarged partial view in elevation of a portion of the illustrative embodiment shown in FIG. 8.

FIG. 1 illustrates a point-contact semiconductor diode rectifier of the type employed in radar microwave receiver apparatus to rectify returned radar pulses. Any of the high burnout semiconductor diodes having high rectification characteristics are preferred and are commercially available, such as the 1N82 or 1N830. The rectifying junction is formed by whisker element **2** contacting the semiconductor element **4** respectively connected to leads **6** and **8**. Silicon is preferred over germanium for element **4** because of its ability to operate at higher temperatures and thereby handle higher powers. Envelope **10** houses the rectifying elements and may be of a hermetically sealed dielectric material or combination metal and ceramic composition. The inherent characteristic of such diode rectifiers is that the microwave energy is intercepted and rectified in a unidirectional manner and the line **11** indicate pictorially the rays of the beamed electromagnetic microwave energy in a plane normal to the envelope. In FIG. 2 a full-wave bridge connected diode network is illustrated with the forward direction of the rectified DC electric current indicated by the direction of the arrow symbols. The network shown consists of half-wave dipoles **20** and **22** each terminated with a diode rectifier element **24** to **27** in an arm of the bridge connected network. The dipole elements **20** and **22** are of the half-wave configuration and may be spaced apart from each other a one-half wavelength at the frequency of the beamed electromagnetic energy.

Referring now to FIG. 3, an array of bridge connected diode networks each with the half-wave dipoles are shown connected in series. Each network is referred to by the numeral **30** and is similar in the bridge connections to the single element network shown in FIG. 2. The DC output of the collective rectified energy is coupled by means of terminals **32** and **33**. In FIG. 4, a similar number of individual bridge connected diode-dipole networks are shown connected in a parallel array. Each network is indicated by the numeral **40**, and the output terminals are indicated as **41** and **42**.

Any number of diode-dipole networks may be provided and in FIG. 5 such a multi-element array is illustrated by mounting on a flexible material **50** which may be rolled or folded into any desired package or enclosed within a capsule to be launched and released at a predetermined point in space. Any flexible material which is pervious to electromagnetic energy is preferred. The total power desired would be the determining factor in a number of individual diode-dipole elements required. In this embodiment, the bridge connected networks **51** are connected in parallel to the output load indicated by terminals **52** and **53**, and representative measurements of electrical characteristics have shown that approximately five watts of DC electrical energy is realizable for each square foot of area of the combined antenna-rectifier. While the dipole elements **54** have been indicated in a particular array, it is within the scope of the invention to stagger the placement of such dipoles to increase the over-all efficiency of the antenna-rectifier.

To further increase the DC powder output, the full-wave bridge connected networks are preferably arranged with a plurality of diodes in series in each arm of the bridge. An illustrative schematic circuit diagram of such a configuration is shown in FIG. 6 wherein seven diodes **60** are shown in each arm of the bridge circuit and are connected in series for a total of twenty-eight diodes in each bridge network. The dipole members will then be the substantially U-shaped end portions **61** at the ends of each brace of seven diodes. In the illustration three such twenty-eight diode bridge networks are shown connected in parallel to terminals **62** and **63**. This closer spacing and compact arrangement has been shown to be a source of improved power output and is capable of a high degree of reliability through the redundant nature of the parallel series connections within each bridge network. If one of the diode rectifiers fails to function the over-all voltage drop across this element would be divided among the six remaining diode rectifiers. If any of the connecting wires between the diode elements should break, the adjacent arms of the other bridge assemblies would take the additional load due to the close proximity of the respective arms to each other. In addition, it is possible to have a number of open connections or inoperative diodes dispersed throughout the array without any serious impairment in performance.

In relation to the array concept to be hereinafter described it may be stated that within a six inch square area ten such individual bridge networks each containing twenty-eight diode rectifiers for a total of 280 diode rectifiers may be deployed in such a manner as to provide

maximum exposed area for each diode as well as the connecting leads. Such an arrangement will be hereinafter referred to as a "module" and a DC output in excess of fourteen watts has been measured for such a module. Any number of such modules could be connected provided for a desired power yield and this module concept readily lends itself to use in certain aerospace applications now to be described.

In FIG. 7 a propelled type of space vehicle **70** is shown wholly supported by means of the transfer and rectification of continuous wave electromagnetic energy via a microwave beam **72**. The source of the microwave energy which may be of the Amplitron type device as described in the aforementioned issued Patent No. 2,933,723 is indicated as **74**. This energy is fed by waveguide means **76** to a transmitting horn **78** to illuminate an ellipsoidal beam forming focusing antenna **80** for the transmission of the microwave beam **72**. It will be appreciated by those skilled in the art that the representations of the microwave generation and transmitting antenna means are pictorial representations to illustrate the usage of the invention in diagrammatic form and the present invention is not limited to any particular source of microwave energy or transmitting antenna assembly. It may be stated the reflector of the antenna assembly is considerably larger than most of the reflectors of the prior art in order to focus a large amount of the microwave power at high altitudes for use in the transfer of energy to space vehicles. Such antenna assemblies may be partially supported in a large hollowed area on the earth's surface or other convenient means of support.

The space vehicle or helicopter **70** can be described as a main body member supporting antenna-rectifier means **82** including a large number of the so-called modules connected together and rigidly supported in a planar parallel array. A motor **84** is supported by the combined body member and the receiving antenna-rectifier means and actuates the rotor **86** of conventional design employed in such self-propelled hovering vehicles. The disclosed vehicle provides for the illumination of the planar array of the semiconductor diode dipole elements by the microwave beam and the direct conversion of the microwave power transmitted by the beam into usable electrical energy for the self-propulsion of the device without any local fuel supply being required.

FIGS. 8 and 9 illustrate a space vehicle **82** comprising a plurality of the combined receiving antenna-rectifier module means for interception and rectification of the electromagnetic microwave energy beam emanating from an earth or mother planet source. A planar array of the antenna-rectifier modules is mechanically supported by means of structural members **90** of any lightweight wood or metal. Insulators **91** positioned coextensive with the members **90** support the diode rectifier array and avoid interference with the receiving and electrical performance characteristics by the structural support members. Carrying forward the module concept of 280 diode rectifiers to provide an approximate power output of 14 watts, it was noted that any number of such modules may be coupled together since the individual module outputs are relatively insensitive to a wide range of load resistances connected to the common output terminals. To achieve the desired electrical output of approximately 120 volts and 250 watts of power, subgroups of four modules each were assembled and parallel connected with an approximate 30 volts available for each subgroup. Four such subgroups were series-connected to result in a total of 4,480 diode rectifiers or 16 modules assembled in a two foot square self-supporting planar parallel array structure. The individual diode rectifiers connected in each arm of the bridge network are indicated by the numeral **92**. An exemplary module configuration would extend within the area delineated by the dotted lines and reference letter A on one side and similar dotted lines and reference letter B on the other side.

A motor **94** is connected to the DC side of the overall array and may be additionally supported by tubular member **95**. A shaft and propulsion means consisting of rotor blades **97** provide for the upward lift of the overall vehicle for the self-supporting of same in space applications. Additional structural support such as interlaced rigging **96** of a high tensile strength material such as nylon or steel wire, as well as bracing member **98**, may be employed for strengthening of the body means to withstand the vibrational forces and downwash from the propulsion means.

In accordance with the well known technology of microwave transmission the combined array of diode rectifiers and propulsion means presents a specific load impedance which must be suitably matched to the transmitted microwave energy beam to result in maximum efficiency. In aerospace applications a mismatch of approximately ten to one may be evident. Matching of the load impedance to a value of approximately 377 ohms as the free space value will be provided by a plurality of coplanar parallel metallic rod members **99** disposed in a grating array in front of the diode rectifiers a predetermined distance. Rod members **99** are linearly disposed and extend in a similar direction as the assembled diode rectifiers. A selected frontal spacing of one-quarter of the wavelength of the microwave frequency being transmitted has been experimentally determined to be suitable for impedance matching purposes. An approximate spacing of two inches between the respective members was preferred for a selected microwave frequency of 2,450 megacycles. Each of the members **90** are provided with lateral sections **100** to support the elongated bar members **101** which in turn maintain the rod members **99** in the desired position. A tubular member **102** of a lightweight metal may also be provided to combine with the motor support member **95** for structural support.

The combined antenna-rectifier array provides a source of electrical energy to render any space vehicle self-supporting. The diode rectifier elements when assembled in the antenna array have been found to be nondirectional with respect to interception of the beamed microwave energy. This represents a large step forward in the utilization of high power microwave energy over the prior art horn-type receiving antennas which must be accurately focused and pointed in a particular direction for the reception of any energy. The connections between the respective members of the diode rectifier array and deployment in the parallel configuration serves to provide maximum exposed area. Such connections and in particular the end loop portions adjacent the terminus of each arm of the bridge networks serves as an efficient dipole for the interception of the microwave energy.

Although it is not intended as a full explanation of the high degree of efficiency attained with the disclosed antenna-rectifier array, it is believed that the whisker elements within the semiconductor diodes themselves are a contributing factor and may function as additional dipole elements. The disclosed embodiment functioned efficiently when illuminated by microwave energy generating a vertically polarized beam. Hence, an efficient and light weight energy conversion apparatus is disclosed which may be self-supporting without the requirement of a large local fuel supply payload.

It may be within the purview of the invention to use the available rectified electrical energy for performing many functions in addition to the actuation of the propulsion means. Hence, communications' payloads may be maintained at predetermined positions in space in a hovering attitude utilizing a portion of the electrical energy available. Relay signals to other such vehicles or return signals to ground stations would then be within the realm of possibility. Such available energy may also be employed for servomechanisms, stabilizing and countertorque systems for the navigation of such vehicles.

The electrical efficiencies realized with the combined

receiving antenna and rectifier means have also provided certain weight advantages over other energy converters in aerospace applications. Examples of such converters would be heat exchangers or solar cells. In comparison to the present invention where five to eight pounds per kilowatt of energy realized is a normal characteristic, other energy conversion means weigh in the vicinity of 150 pounds per kilowatt of realizable energy. The inherent advantages of the present invention are therefore apparent. While the technology in the diode rectifier art is being continually advanced, new diode power rectifiers as well as integrated circuit techniques are readily available to future configurations of the present invention. The so-called Schottky barrier diodes could be employed to produce combined antenna-rectifier means weighing even less than two pounds per kilowatt of available energy.

Although the foregoing detailed description has referred to DC power rectification it will be evident that with suitable circuit components low frequency AC energy may also be made available. In addition, other propulsion means may be readily substituted using electrical energy. The embodiments disclosed herein are illustrative only and other modifications or alterations will be apparent to those skilled in the art which do not depart from the scope of the broadest aspects of the present invention as defined in the appended claims.

What is claimed is:

1. A space vehicle comprising:

body means;

said body means including spaced structural support members;

combined antenna and DC electrical energy rectification means for the interception and rectification of incident high frequency electromagnetic microwave energy carried by said support members in a planar parallel array;

said rectification means comprising a plurality of four arm full-wave bridge connected rectifier circuit networks each having a plurality of unidirectional semiconductors in each arm;

said networks being electrically interconnected to common output terminals;

electrically operable propulsion means comprising a motor and rotor members carried by said body means and connected to said terminals for the utilization of said rectified DC energy; and

means for matching the load impedance of said combined antenna and electrical energy rectification means to the incident microwave energy.

2. A space vehicle according to claim **1** wherein said load impedance matching means are arranged in a coplanar array coextensive with said antenna and energy rectification means array, and spaced therefrom a distance of approximately one-quarter of a wavelength at the frequency of the microwave energy.

3. A space vehicle according to claim **2** wherein said load impedance matching means comprise a plurality of parallel disposed elongated metallic members.

ABSTRACT OF THE DISCLOSURE

A combined antenna and conversion mechanism for reception of beamed high frequency electromagnetic energy in space including a large array of unidirectional current semiconductor rectifier devices. A self-supporting space vehicle utilizing the rectified DC electrical energy for propulsion is disclosed in an illustrative embodiment.

The present invention relates in general to the transfer of energy by means of an electromagnetic wave beam and more particularly to interception and rectification of such energy into low frequency electrical DC energy with a high degree of efficiency.

Improved technology in the field of microwave energy generation at superpower levels has resulted in the realization of electrical energy transmission over considerable distances for remote energization of devices or vehicles without the aid of wires. The transmission of microwave electromagnetic energy into space has been commonly employed in the radar pulse echo systems for the detection and orientation of desired objects within a predetermined scanning range of a transmitting antenna. Beams of a similar nature may now be employed for other useful purposes and the advantages attendant the utilization of electromagnetic energy in the microwave region in contrast with other wavelengths may now be enumerated.

Microwaves have been generally defined as high frequency radio waves whose wavelength is less than 30 centimeters, with a lower wavelength limit on the order of 1 millimeter sometimes being applied to what is commonly referred to as the "microwave region." The superiority of high frequency microwaves is due in part to the fact that it is generally desirable to focus the transmitted energy so as to achieve a high power density at a remote point or area with respect to a given power source. In accordance with the laws of optics, the sharpness of the microwave beam produced by a transmitting antenna varies as the ratio of antenna dimensions to the wavelength of the transmitted energy. Therefore, for a given or desired power density or beam sharpness, a decrease in the wavelength of the transmitted energy permits a corresponding decrease in the dimensions of the antenna. From the standpoint of mechanical considerations, it is desirable to employ small antennas and other components, and it is therefore advantageous to employ high frequency energy of very short wavelength. In addition, the difficulties encountered in long wave transmission as a result of natural and man-made interference or noise do not occur with any appreciable significance at microwave frequencies. Further, in aerospace applications with considerable distances separating the transmitter at an earth or mother planet location and the employment of shorter wavelength beamed energy is preferred since longer wave signals will generallly be reflected at certain altitudes by reflecting layers in the atmosphere.

In view of certain losses due to absorption which may occur in the atmosphere, microwaves in the region having the approximate bounds of 2 and 30 centimeters are readily adaptable to the convenient radiation of power to remote points without the utilization of wires. The preferred wavelengths are of the order of 5 or 10 centimeters to provide efficient focusing with existing transmitting antenna systems which may be maintained at a reasonable size. An illustrative device of the superpower high frequency microwave generators operative in the desired band is the so-called Amplitron which is an amplifier having a broad bandwidth and excellent performance characteristics for the focusing of the beam. Such devices are capable of producing 15 or 20 kilowatts of average continuous wave power in the neighborhood of 10 centimeters in wavelength with capabilities expected in the region of 500 kilowatts or more average power with 50 megawatts peak power. A complete description of such devices may be had by referring to Patent No. 2,933,723 issued Apr. 19, 1960 to William C. Brown and assigned to the assignee of the present invention.

With microwave energy capable of being generated and directed over longer distances conversion of such high frequency electromagnetic energy is of paramount concern. One conversion mechanism in the prior art involves direct conversion of such energy into heat which may then be utilized directly or indirectly for propulsion or generation of flight-producing forces. Examples of such devices for heat energy exchange as well as space vehicles utilizing such energy may be noted in Patent No. 3,174,705, issued Mar. 23, 1965, to D. Schiff et al., as well as U.S. Letters Patent No. 3,083,528, issued Apr. 2, 1963 and No. 3,114,517, issued Dec. 17, 1963, to William C. Brown. The heat exchanger method of conversion of electromagnetic energy into useful power is limited by the overall efficiencies of approximately 25 percent in the conversion of heat into mechanical or electrical work. Desirable, therefore, would be the direct rectification of the high frequency electromagnetic energy into low frequency electrical energy for the operation of many useful aerospace devices as well as systems.

The present invention has for its primary object the conversion of high frequency electromagnetic energy in the microwave region directly into low frequency electrical energy.

A further object of the present invention is the provision of a combined nondirectional receiving antenna and microwave electromagnetic energy to low frequency electrical energy conversion means in a unitary structure.

A still further object of the present invention is a provision of a new and novel combined nondirectional receiving antenna and microwave to DC energy converter for aerospace applications.

Another object of the present invention is the provision of a new and novel nondirectional receiving antenna and microwave to DC energy converter having a high degree of efficiency.

Still another object of the present invention is the provision of a new and novel aerospace vehicle with nondirectional receiving antenna and microwave to DC energy converter means with said vehicle being capable of being supported by its own energy generation means at a distance spaced apart from the power generation means.

In accordance with the teachings of the present invention, the above and other objects are achieved by the employment of efficient unidirectional microwave power rectifiers and dipole antenna means. Such rectifying devices, while being individually limited in power-handling capabilities, normally in the order of fractions of watts, have been found to be highly efficient means for the rectification of microwave power when assembled in large numbers in various arrays. It is interesting to note that the observed collective efficiency was on the order of 40 to 70 percent. In an illustrative embodiment, point-

contact semiconductor diodes were arranged in four arm bridge connected networks with the networks interconnected in various configurations such as series, parallel and series-parallel.

In discussing aerospace applications, an additional problem is encountered in the beaming of microwave energy to a remote point and the interception and utilization of such electrical energy. In such applications the advantages of a vehicle which may be maintained in space for indeterminate periods of time without employing a local fuel source are readily apparent. Such devices could readily provide communication networks, surveillance functions using radar techniques along with numerous other functions. The acapture of the beamed high frequency electromagnetic energy raises the need for an efficient antenna means capable of intersecting the beam at high altitudes. Conventional techniques employed in microwave radar usage such as receiving antenna horns are capable of intersecting only a small portion of the beam energy and add considerable weight in applications involving heavier-than-air vehicles. In an exemplary embodiment of the invention a space vehicle, namely a helicopter, is disclosed for either moving flight or a stationary location with self-supporting electrically operative propulsion means. The semi-conductor diode rectifier arrays have been demonstrated to fulfill the receiving antenna functions as well as the electrical energy rectification means in a highly efficient manner. Such combined antenna and rectifier means has also assisted in reduction of the weight problem in airborne devices. Further, it has provided a nondirectional means for the interception of the microwave energy to thereby reduce the problems of focusing inherent in prior art directional horn type receiving antennas.

With the above features, advantages and objects in mind the invention will now be described by reference to the following detailed description together with the accompanying drawings in which:

FIG. 1 is a perspective view of an illustrative diode rectifier;

FIG. 2 is a schematic circuit diagram of a bridge connected diode network with dipole antenna means;

FIG. 3 is a schematic circuit diagram of a plurality of bridge connected networks arranged in series;

FIG. 4 is a schematic circuit diagram of a parallel bridge connected network array;

FIG. 5 is a perspective view of an illustrative embodiment of a combined antenna and rectifier array in a folded or rolled up configuration;

FIG. 6 is a schematic circuit diagram illustrating the bridge connected diode array incorporated in the aerospace vehicle shown in FIG. 7;

FIG. 7 is a schematic representation in elevation illustrative of a heavier-than-air aerospace vehicle incorparating the structure of the present invention;

FIG. 8 is a perspective view of the aerospace vehicle embodiment as viewed from the under portion thereof; and

FIG. 9 is an enlarged partial view in elevation of a portion of the illustrative embodiment shown in FIG. 8.

FIG. 1 illustrates a point-contact semiconductor diode rectifier of the type employed in radar microwave receiver apparatus to rectify returned radar pulses. Any of the high burnout semiconductor diodes having high rectification characteristics are preferred and are commercially available, such as the 1N82 or 1N830. The rectifying junction is formed by whisker element **2** contacting the semiconductor element **4** respectively connected to leads **6** and **8**. Silicon is preferred over germanium for element **4** because of its ability to operate at higher temperatures and thereby handle higher powers. Envelope **10** houses the rectifying elements and may be of a hermetically sealed dielectric material or combination metal and ceramic composition. The inherent characteristic of such diode rectifiers is that the microwave energy is intercepted and rectified in a unidirectional manner and the line **11** indicate pictorially the rays of the beamed electromagnetic microwave energy in a plane normal to the envelope. In FIG. 2 a full-wave bridge connected diode network is illustrated with the forward direction of the rectified DC electric current indicated by the direction of the arrow symbols. The network shown consists of half-wave dipoles **20** and **22** each terminated with a diode rectifier element **24** to **27** in an arm of the bridge connected network. The dipole elements **20** and **22** are of the half-wave configuration and may be spaced apart from each other a one-half wavelength at the frequency of the beamed electromagnetic energy.

Referring now to FIG. 3, an array of bridge connected diode networks each with the half-wave dipoles are shown connected in series. Each network is referred to by the numeral **30** and is similar in the bridge connections to the single element network shown in FIG. 2. The DC output of the collective rectified energy is coupled by means of terminals **32** and **33**. In FIG. 4, a similar number of individual bridge connected diode-dipole networks are shown connected in a parallel array. Each network is indicated by the numeral **40**, and the output terminals are indicated as **41** and **42**.

Any number of diode-dipole networks may be provided and in FIG. 5 such a multi-element array is illustrated by mounting on a flexible material **50** which may be rolled or folded into any desired package or enclosed within a capsule to be launched and released at a predetermined point in space. Any flexible material which is pervious to electromagnetic energy is preferred. The total power desired would be the determining factor in a number of individual diode-dipole elements required. In this embodiment, the bridge connected networks **51** are connected in parallel to the output load indicated by terminals **52** and **53**, and representative measurements of electrical characteristics have shown that approximately five watts of DC electrical energy is realizable for each square foot of area of the combined antenna-rectifier. While the dipole elements **54** have been indicated in a particular array, it is within the scope of the invention to stagger the placement of such dipoles to increase the overall efficiency of the antenna-rectifier.

To further increase the DC powder output, the full-wave bridge connected networks are preferably arranged with a plurality of diodes in series in each arm of the bridge. An illustrative schematic circuit diagram of such a configuration is shown in FIG. 6 wherein seven diodes **60** are shown in each arm of the bridge circuit and are connected in series for a total of twenty-eight diodes in each bridge network. The dipole members will then be the substantially U-shaped end portions **61** at the ends of each brace of seven diodes. In the illustration three such twenty-eight diode bridge networks are shown connected in parallel to terminals **62** and **63**. This closer spacing and compact arrangement has been shown to be a source of improved power output and is capable of a high degree of reliability through the redundant nature of the parallel series connections within each bridge network. If one of the diode rectifiers fails to function the over-all voltage drop across this element would be divided among the six remaining diode rectifiers. If any of the connecting wires between the diode elements should break, the adjacent arms of the other bridge assemblies would take the additional load due to the close proximity of the respective arms to each other. In addition, it is possible to have a number of open connections or inoperative diodes dispersed throughout the array without any serious impairment in performance.

In relation to the array concept to be hereinafter described it may be stated that within a six inch square area ten such individual bridge networks each containing twenty-eight diode rectifiers for a total of 280 diode rectifiers may be deployed in such a manner as to provide

maximum exposed area for each diode as well as the connecting leads. Such an arrangement will be hereinafter referred to as a "module" and a DC output in excess of fourteen watts has been measured for such a module. Any number of such modules could be connected provided for a desired power yield and this module concept readily lends itself to use in certain aerospace applications now to be described.

In FIG. 7 a propelled type of space vehicle **70** is shown wholly supported by means of the transfer and rectification of continuous wave electromagnetic energy via a microwave beam **72**. The source of the microwave energy which may be of the Amplitron type device as described in the aforementioned issued Patent No. 2,933,723 is indicated as **74**. This energy is fed by waveguide means **76** to a transmitting horn **78** to illuminate an ellipsoidal beam forming focusing antenna **80** for the transmission of the microwave beam **72**. It will be appreciated by those skilled in the art that the representations of the microwave generation and transmitting antenna means are pictorial representations to illustrate the usage of the invention in diagrammatic form and the present invention is not limited to any particular source of microwave energy or transmitting antenna assembly. It may be stated the reflector of the antenna assembly is considerably larger than most of the reflectors of the prior art in order to focus a large amount of the microwave power at high altitudes for use in the transfer of energy to space vehicles. Such antenna assemblies may be partially supported in a large hollowed area on the earth's surface or other convenient means of support.

The space vehicle or helicopter **70** can be described as a main body member supporting antenna-rectifier means **82** including a large number of the so-called modules connected together and rigidly supported in a planar parallel array. A motor **84** is supported by the combined body member and the receiving antenna-rectifier means and actuates the rotor **86** of conventional design employed in such self-propelled hovering vehicles. The disclosed vehicle provides for the illumination of the planar array of the semiconductor diode dipole elements by the microwave beam and the direct conversion of the microwave power transmitted by the beam into usable electrical energy for the self-propulsion of the device without any local fuel supply being required.

FIGS. 8 and 9 illustrate a space vehicle **82** comprising a plurality of the combined receiving antenna-rectifier module means for interception and rectification of the electromagnetic microwave energy beam emanating from an earth or mother planet source. A planar array of the antenna-rectifier modules is mechanically supported by means of structural members **90** of any lightweight wood or metal. Insulators **91** positioned coextensive with the members **90** support the diode rectifier array and avoid interference with the receiving and electrical performance characteristics by the structural support members. Carrying forward the module concept of 280 diode rectifiers to provide an approximate power output of 14 watts, it was noted that any number of such modules may be coupled together since the individual module outputs are relatively insensitive to a wide range of load resistances connected to the common output terminals. To achieve the desired electrical output of approximately 120 volts and 250 watts of power, subgroups of four modules each were assembled and parallel connected with an approximate 30 volts available for each subgroup. Four such subgroups were series-connected to result in a total of 4,480 diode rectifiers or 16 modules assembled in a two foot square self-supporting planar parallel array structure. The individual diode rectifiers connected in each arm of the bridge network are indicated by the numeral **92**. An exemplary module configuration would extend within the area delineated by the dotted lines and reference letter A on one side and similar dotted lines and reference letter B on the other side.

A motor **94** is connected to the DC side of the overall array and may be additionally supported by tubular member **95**. A shaft and propulsion means consisting of rotor blades **97** provide for the upward lift of the overall vehicle for the self-supporting of same in space applications. Additional structural support such as interlaced rigging **96** of a high tensile strength material such as nylon or steel wire, as well as bracing member **98**, may be employed for strengthening of the body means to withstand the vibrational forces and downwash from the propulsion means.

In accordance with the well known technology of microwave transmission the combined array of diode rectifiers and propulsion means presents a specific load impedance which must be suitably matched to the transmitted microwave energy beam to result in maximum efficiency. In aerospace applications a mismatch of approximately ten to one may be evident. Matching of the load impedance to a value of approximately 377 ohms as the free space value will be provided by a plurality of coplanar parallel metallic rod members **99** disposed in a grating array in front of the diode rectifiers a predetermined distance. Rod members **99** are linearly disposed and extend in a similar direction as the assembled diode rectifiers. A selected frontal spacing of one-quarter of the wavelength of the microwave frequency being transmitted has been experimentally determined to be suitable for impedance matching purposes. An approximate spacing of two inches between the respective members was preferred for a selected microwave frequency of 2,450 megacycles. Each of the members **90** are provided with lateral sections **100** to support the elongated bar members **101** which in turn maintain the rod members **99** in the desired position. A tubular member **102** of a lightweight metal may also be provided to combine with the motor support member **95** for structural support.

The combined antenna-rectifier array provides a source of electrical energy to render any space vehicle self-supporting. The diode rectifier elements when assembled in the antenna array have been found to be nondirectional with respect to interception of the beamed microwave energy. This represents a large step forward in the utilization of high power microwave energy over the prior art horn-type receiving antennas which must be accurately focused and pointed in a particular direction for the reception of any energy. The connections between the respective members of the diode rectifier array and deployment in the parallel configuration serves to provide maximum exposed area. Such connections and in particular the end loop portions adjacent the terminus of each arm of the bridge networks serves as an efficient dipole for the interception of the microwave energy.

Although it is not intended as a full explanation of the high degree of efficiency attained with the disclosed antenna-rectifier array, it is believed that the whisker elements within the semiconductor diodes themselves are a contributing factor and may function as additional dipole elements. The disclosed embodiment functioned efficiently when illuminated by microwave energy generating a vertically polarized beam. Hence, an efficient and light weight energy conversion apparatus is disclosed which may be self-supporting without the requirement of a large local fuel supply payload.

It may be within the purview of the invention to use the available rectified electrical energy for performing many functions in addition to the actuation of the propulsion means. Hence, communications' payloads may be maintained at predetermined positions in space in a hovering attitude utilizing a portion of the electrical energy available. Relay signals to other such vehicles or return signals to ground stations would then be within the realm of possibility. Such available energy may also be employed for servomechanisms, stabilizing and countertorque systems for the navigation of such vehicles.

The electrical efficiencies realized with the combined

receiving antenna and rectifier means have also provided certain weight advantages over other energy converters in aerospace applications. Examples of such converters would be heat exchangers or solar cells. In comparison to the present invention where five to eight pounds per kilowatt of energy realized is a normal characteristic, other energy conversion means weigh in the vicinity of 150 pounds per kilowatt of realizable energy. The inherent advantages of the present invention are therefore apparent. While the technology in the diode rectifier art is being continually advanced, new diode power rectifiers as well as integrated circuit techniques are readily available to future configurations of the present invention. The so-called Schottky barrier diodes could be employed to produce combined antenna-rectifier means weighing even less than two pounds per kilowatt of available energy.

Although the foregoing detailed description has referred to DC power rectification it will be evident that with suitable circuit components low frequency AC energy may also be made available. In addition, other propulsion means may be readily substituted using electrical energy. The embodiments disclosed herein are illustrative only and other modifications or alterations will be apparent to those skilled in the art which do not depart from the scope of the broadest aspects of the present invention as defined in the appended claims.

What is claimed is:

1. A space vehicle comprising:

body means;

said body means including spaced structural support members;

combined antenna and DC electrical energy rectification means for the interception and rectification of incident high frequency electromagnetic microwave energy carried by said support members in a planar parallel array;

said rectification means comprising a plurality of four

arm full-wave bridge connected rectifier circuit networks each having a plurality of unidirectional semiconductors in each arm;

said networks being electrically interconnected to common output terminals;

electrically operable propulsion means comprising a motor and rotor members carried by said body means and connected to said terminals for the utilization of said rectified DC energy; and

means for matching the load impedance of said combined antenna and electrical energy rectification means to the incident microwave energy.

2. A space vehicle according to claim **1** wherein said load impedance matching means are arranged in a coplanar array coextensive with said antenna and energy rectification means array, and spaced therefrom a distance of approximately one-quarter of a wavelength at the frequency of the microwave energy.

3. A space vehicle according to claim **2** wherein said load impedance matching means comprise a plurality of parallel disposed elongated metallic members.

[57] **ABSTRACT**

Electromagnetic wave energy is converted into electric power with an array of mutually insulated electromagnetic wave absorber elements each responsive to an electric field component of the wave as it impinges thereon. Each element includes a portion tapered in the direction of wave propagation to provide a relatively wideband response spectrum. Each element includes an output for deriving a voltage replica of the electric field variations intercepted by it. Adjacent elements are positioned relative to each other so that an electric field subsists between adjacent elements in response to the impinging wave. The electric field results in a voltage difference between adjacent elements that is fed to a rectifier to derive d.c. output power. The element pairs may be arranged in a two-dimensional array to provide power conversion of randomly polarized electromagnetic waves, such as sunlight.

ELECTROMAGNETIC WAVE ENERGY CONVERTER

ORIGIN OF THE INVENTION

The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958, Public Law 85-568 (72 Stat. 435; 42 U.S.C. 2457).

FIELD OF INVENTION

The present invention relates generally to devices for converting electromagnetic wave energy into electric power and, more particularly, to a device including a number of relatively closely spaced electromagnetic wave absorber elements having tapered portions responsive to wide band electromagnetic wave radiation.

BACKGROUND OF THE INVENTION

Devices for converting radiant energy into usable power have been considered extensively in the past. Presently, the most commonly utilized devices for converting radiant energy into usable power are solar cells which are adapted to convert solar energy directly into electricity for power generating purposes. Solar cells generally include oppositely doped semiconductor junctions which generate current in response to solar energy impinging thereon. Solar cells depend for their operation on quantum properties of light energy to provide charge separation and hence current flow in the junction region. To date, the maximum efficiency of solar cells in converting solar energy into electric energy is approximately 13 percent. In addition to the relatively low conversion efficiency of solar energy into electric power, solar cells are very expensive, as well as fragile, and usually must be mounted on a rigid, preferably flat substrate. The requirement for a rigid, flat substrate frequently substantially increases the combined cost of the solar cells and their supporting structure; if the supporting structure is a spacecraft panel, problems of folding the panel and maintaining it in a rigid condition in use are encountered.

BRIEF DESCRIPTION OF THE INVENTION

In accordance with the present invention, the wave properties of electromagnetic energy are utilized to convert wide band electromagnetic wave energy into usable electric power. The wide band energy impinges on an array of tapered absorber elements mutually insulated from each other. The length, base area, and separation of the elements are such that relatively wide band energy can be absorbed. To achieve maximum conversion of wide band energy, each element has a length, in the direction of wave propagation, equal to several wavelengths of the longest wavelength energy to be converted. Adjacent elements have spaced, sloping converging sides to enable maximum conversion of energy wavelengths in the spectrum to be converted. A voltage replica of the electric field variations absorbed by each element is derived at an output of each element. The difference between the voltage variations derived from adjacent elements is derived and supplied to a rectifier to provide the power conversion. To maximize the voltage difference, bases of adjacent absorber elements are spaced from each other by less than one wave length and preferably less than ½ wavelength, of the received energy. The close spacing, relatively long length and tapered sides also enable the absorber elements to function effectively as absorbers and prevent substantial re-radiation and reflection of the energy impinging thereon because the wave radiation is trapped in the converging interstices between the abosrbing elements.

In a preferred embodiment, the absorbers are formed of metallic elements, such as copper or other suitable material; however, absorbers may consist of dielectric elements which function to direct the electromagnetic wave energy onto an electromagnetic wave energy-to-electric voltage converter that derives a voltage replica of the wave energy.

The invention may be utilized in conjunction with converting wave energy from the microwave region through the visible light spectrum. If the invention is utilized for wave lengths in the solar spectrum, it is ideally suited for use as a solar energy-to-electric power converter. In such a configuration, the absorber elements and electric components utilized for converting the voltage wave replicas into electric power might be formed utilizing integrated circuit type manufacturing processes.

If the device is utilized for absorbing plane polarized electromagnetic waves, adjacent elements in the direction of the wave electric field are aligned with each other in pairs such that maximum electric field variations are derived between them but adjacent elements at right angles to the electric field are packed as close as possible to each other without electric contact, to maximize the active absorber area. If the electromagnetic wave radiation is circularly or randomly polarized, as in the case of solar energy, a two-dimensional array of elements is provided. The elements of the two-dimensional array are positioned in mutually orthogonal directions having aligned columns and rows, and the elements preferably have symmetrical bases, such as a square or circle. Voltage differences are derived between adjacent pairs in both orthogonal directions to provide maximum conversion efficiency of the circularly or randomly polarized wave energy.

Because the conversion process is in response to the wave properties of the impinging electromagnetic wave energy, rather than the quantum properties of such waves, and because of the small number of loss mechanisms individually and collectively optimal, it is believed possible to achieve conversion efficiencies considerably greater than existing solar cell type devices. A major advantage of the present invention is the separation of the wave absorption means and the conversion means permitting each to be individually optimized for the incident wave electromagnetic power spectrum. Another major advantage is that by suitable choice of geometry for the absorbing elements the device can be made to match the incident radiation spectrum. There is no known means of achieving this desirable result with present art solar cells. Another advantage of the present invention is that it does not utilize temperature-sensitive active semiconductor elements, for the basic absorption process; the only semiconductor components are passive diodes. A further advantage of the present invention is that the substrate on which the elements are mounted can be mechanically flexible, to substantially eliminate many of the problems inherent with prior art fragile solar cells mounted on rigid substrates.

It is, accordingly, an object of the present invention to provide a new and improved device for converting electromagnetic wave energy into electric power.

Another object of the invention is to provide a new and improved device for converting wide band electromagnetic wave energy into electric power with relatively high efficiency, utilizing the wave properties of the energy.

An additional object of the invention is to provide a new and improved device for converting circularly or randomly polarized electromagnetic wave energy into electric power in response to electric field gradients.

A further objet of the invention is to provide a relatively inexpensive device for converting electromagnetic wave energy into electric power, which device is relatively temperature-insensitive and can be mounted on a flexible substrate.

An additional object is to provide a new and improved integrated circuit type device for converting solar energy into electric power.

An additional object is to provide a new and improved means of matching the response of the device to the incident electromagnetic wave spectrum.

The above and still further objects, features and advantages of the present invention will become apparent upon consideration of the following detailed description of several specific embodiments thereof, especially when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 is a perspective view schematically illustrating the principles of the present invention;

FIG. 2 is a perspective diagram illustrating an embodiment of the invention particularly adapted for converting solar energy into electric power; and

FIG. 3 is a side sectional view of the embodiment illustrated in FIG. 2, along the lines 3—3.

DETAILED DESCRIPTION OF THE DRAWING

Reference is now made to FIG. 1 of the drawing wherein is illustrated a pair of mutually insulated, substantially identical, pyramidal or conical, aligned and relatively closely packed, preferably metallic, as copper or other suitable material, electromagnetic wave absorber elements **11** and **12** which are responsive to plane polarized wide band electromagnetic wave energy that is propagating in a direction indicated by arrow **14** and has an electric field with a gradient in a direction indicated by arrow **15.** Elements **11** and **12** are constructed so that the shapes of every cross section parallel to their bases **13** are similar; the cross-sectional areas decrease for increasing distances from the bases **13** of the elements. Each of elements **11** and **12** includes a co-planar base **13**, which may have any desired configuration, such as a rectangle, square or circle, that lies in a plane at right angles to the direction of wave propagation and is parallel to the electric field gradient **15.** Elements **11** and **12** have a substantial height, L, or length in the direction of wave energy propagation, between their base **13** and apex **17.** The height is generally several (up to approximately seventy five) wave lengths of the longest wavelength of the incident electromagnetic energy. Elements **11** and **12** include adjacent, tapered side surfaces **16** that converge toward base **13** and are positioned relative to each other to intercept the electric field **15** and absorb energy over a wide band of the electromagnetic wave. The apex of absorber elements **11** and **12** may be truncated in which case L is the length of the truncated absorber elements.

Voltage variations derived in elements **11** and **12** in response to the electric field variations of the electromagnetic wave energy impinging on surfaces **16** are transduced or converted into an electric voltage at terminals **21** and **22** of the elements. The voltages at terminals **21** and **22** are replicas of the electric field variations impinging on absorber elements **11** and **12,** whereby the voltage difference between terminals **21** and **22** is proportional to the electric field gradient established by the plane polarized wave between facing surfaces **16** of elements **11** and **12.**

The centerline spacing between adjacent elements **11** and **12** is such that for the incident electromagnetic wave spectrum, maximum voltage between **21** and **22** occurs. It is of the order of a wavelength or less of the incident electromagnetic energy. The present invention responds to this voltage difference as derived over the desired spectrum of the incident wave energy, to convert the wave energy into electric power.

The voltage difference between terminals **21** and **22** is converted into useful d.c. electric power by a rectifier **23** and a filter capacitor **24,** the voltage across which is supplied to a suitable external load, such as resistor **25.** The cathode is connected between the anode of the rectifier diode and terminal **22.** It is to be understood that a full wave rectifier can be employed and that the d.c. voltage developed across external load **25** can be supplied to any suitable device, such as a d.c.-to-a.c. power frequency device.

The breadth,B, and depth,D, of base **13** as well as the length, L, and spacing between the elements **11** and **12** enable the band width to which the elements **11** and **12** are responsive to be adjusted to provide optimum matching to the spectrum of the electromagnetic wave energy impinging on absorber elements **11** and **12.** Close spacing between adjacent elements **11** and **12,** in addition to enabling the electric field gradient to be coupled with the greatest voltage difference to terminals **21** and **22,** enables the electric field to be effectively trapped in the converging interstices between facing, adjacent elements **11** and **12.** Trapping of the electric field variations occurs because elements **11** and **12** are absorptive to the electric electromagnetic wave energy, whereby the energy is not reflected and re-radiated from the elements.

Because the device of FIG. **1** is responsive to a plane polarized electromagnetic wave, it is preferable for the depth, D, of each of the elements **11** and **12** to be relatively narrow, less than ¼ wave length, so that adjacent elements (not shown) can be packed as closely as possible to either side of elements **11** and **12** in the horizontal direction. Close packing of the elements enables maximum conversion of the electromagnetic wave energy into electric power over the entire area of an array which may be fabricated out of a multiplicity of element pairs as illustrated in FIG. **1.** It is to be noted that the device of FIG. **1** is responsive most efficiently to electromagnetic waves polarized so that the E field is in a plane parallel or coplanar with the long dimension of bases **13.** If the electromagnetic wave polarization direction were rotated 90°, there would be no substantial electric field variation between the adjacent elements **11** and **12** and there would be substantially zero

voltage developed between terminals **21** and **22** with a resulting zero conversion of electromagnetic wave energy into electric power.

The power of the electromagnetic wave incident on absorber elements **11** and **12** is the incident power density times the effective area of the two elements and can thereby be stated approximately as: $2(\bar{E}\times\bar{H})BD$, where $\bar{E}$ and $\bar{H}$ are respectively the electric and magnetic fields of the wave energy. The power indicated by the equation is available so that it can be converted into electric power supplied to a load, except for losses in elements **11** and **12**, rectification, and stray losses. The losses of elements **11** and **12** are principally due to skin effect or di-electric losses, while the rectifier losses are the series resistance of the diode and stray losses are of the capacitor, and supporting substrate for elements **11** and **12**. Stray losses can be minimized by locating elements **11** and **12** on a low loss dielectric substrate to minimize loss currents between the abosrber terminals.

The maximum wavelength restriction (about 75λ of the longest wavelength of the received spectrum) is provided to enable the shortest wavelength of the desired spectrum to be trapped between adjacent elements and to provide a relatively large surface area for extracting power from it. If the maximum wavelength restriction, which corresponds approximately with the length of a cone in an eyeball of a mammal (about 75λ of the longest wavelength of the received spectrum), is exceeded by the incident electromagnetic energy spectrum, then the voltage output between terminals **21–22** of the device decreases.

If the device of FIG. **1** is utilized to convert plane polarized microwave electromagnetic wave energy into electric power, the rectifier circuit can be connected to the terminals by a coaxial cable having a center conductor connected directly to terminal **21** and a shielded outer conductor, possibly with a conventional balun, connected to terminal **22**. In the alternative, the rectifier circuit can be connected to elements **11** and **12** by a wave guide excited by the voltage difference between terminals **21** and **22** so that propagation in the wave guide is in one of the transverse electric modes, such as TE_{01}. In such a configuration, upper and lower conducting surfaces of a rectangular wave guide, between which the electric field is developed, are respectively connected to terminals **21** and **22**.

One microwave absorber actually constructed and tested in accordance with the present invention includes a pair of sheet copper pyramidal elements **11** and **12** having a length (L) of 13.3 centimeters, a breadth (B) of 6.3 centimeters, and a depth (D) of 2.0 centimeters. This absorber pair had a center frequency of approximately 475 Mhz and a pass band between approximately 200 and 700 Mhz. Increasing the length of the abosrber elements, without any changes in the base dimensions of the pyramid, lowered the pass band center frequency, as well as the upper and lower cut-off frequencies.

The basic converter structure of FIG. **1** can be modified, as illustrated in FIG. **2**, to respond to circularly polarized electromagnetic waves or randomly polarized electromagnetic waves, as subsist in solar energy. In FIG. **2**, a multiplicity of absorber elements **31** are arranged in a two-dimensional array of aligned orthogonally directed columns and rows. Elements **31** are mutually insulated from each other and mounted on a dielectric substrate **32**, which is preferably flexible but may be rigid. Each of elements **31** preferably has a symmetrical base and cross section parallel to the base, which may be either circular or square, to enable equal voltages to be derived between adjacent ones of elements **31** in the two orthogonal directions in response to orthogonal electric field components at the same wavelength. Thereby, the total array power output of FIG. **2** is insensitive to the polarization direction of the energy impinging thereon and the array can respond to circularly polarized, as well as randomly polarized electromagnetic wave energy.

To convert the electromagnetic wave energy impinging on elements **31** into electric power, adjacent elements are interconnected with each other by a half wave rectifying network similar to that illustrated in FIG. **1**. In particular, aligned vertical elements **31*a***, **31*b***, and **31*c*** are interconnected so that the anodes of rectifier diodes **33**, connected to elements **31*a*** and **31*c*** (which are separated from each other by element **31*b***) are connected directly to the elements, while the cathodes of the rectifier diodes are connected to one electrode of different capacitors **34**, the other electrodes which have a common connection to element **31*b***. Similarly, horizontally aligned elements **31*a***, **31*d***, and **31*e*** are connected to rectifier circuits such that the center element of the triad has a common connection to a pair of capacitors **34** which are connected to the cathodes of diodes **33**, having anodes connected to be responsive to the voltage replicas respectively derived by absorber element pairs **31*a*–31*d*** and **31*e*–31*d***. D. C. voltages developed across capacitors **34** are supplied to a matrix of load resistors **135**, one of which is connected across each of the capacitors.

Elements **31** of FIG. **2** are illustrated as frustoconical structures having upper bases with considerably smaller areas than the bases of the elements that are secured to substrate **32**. The frusto-conical configuration is preferred in certain instances because sharp points, as illustrated in the pyramidal elements **11** and **12**, FIG. **1**, may have a tendency to fracture.

To enable the structure illustrated in FIG. **2** to function as a device for converting solar electromagnetic wave energy, which has the majority of its power in the spectrum from 0.3 to 1.1 microns, into d.c. power, the element dimensions and inter-element spacing must be on the order of a micron, whereby integrated circuit techniques are preferably employed in fabrication. To this end, a solar energy converter in accordance with the present invention may take the form illustrated by the cross-sectional view illustrated in FIG. **3** but not limited to this embodiment. In FIG. **3**, electrically conductive cones **31*a***, **31*b***, and **31*c*** project from surface **35** of substrate **32**. Alternate ones of cones **31**, such as cones **31*a*** and **31*c***, are ohmically connected to a P-doped regions **36** of substrate **32**, which are formed on surface **35** of substrate **32** in super-position with the bases of cones **31*a*** and **31*c***. A junction is formed between P-doped regions **36** and N-doped regions **37** which are formed in substrate **32** beneath P-doped regions **36**. Regions **36** and **37** respectively correspond with the anode and cathode of diodes **33** connected to cones **31*a*** and **31*c***, FIG. **2**. Annular, dielectric oxide films **42** are formed on face **35** over the intersections between the otherwise exposed portions of the junctions between regions **36** and **37**. Oxide films **42** cover the peripheries of P-doped regions **36** and the inner circumference of N-doped regions **37**. On the portion of

P-doped regions **36** not covered by oxide films **42** and the inner radial portion of the films, metal elements **31***a* and **31***c* are placed. The bases of elements **31***a* and **31***c* are ohmically connected to P-doped regions **36.** Annular, metal films **38** are formed on face **35** in superposition with the otherwise exposed regions **37** to form ohmic contacts with the N-doped regions. Metal films **38** are electrically insulated from elements **31***a* and **31***c* by dielectric films **42** which are disposed between metal films and elements. Metal film **39** is formed on face **35** at the base of element **31***b* and is electrically connected to the base. The areas **41** of substrate **32** between adjacent metal films **38** and **39** form dielectrics for capacitors **34,** having electrodes comprised of the metal film portions **38** and **39.** A d.c. load is connected between metal film portions **38** and **39** so that the film portions form load terminals.

The structure of FIG. 3 is formed by diffusing P and N regions **36** and **37** onto surface **35** of substrate **32,** utilizing conventional integrated circuit techniques. Regions **36** and **37** are diffused only onto the areas beneath and slightly to the sides of where cones **31***a* and **31***d* are to be located. Thereafter, annular oxide regions **42** are formed over the exterior portion of P-doped region **36** and over a slight segment of the interior of N-doped region **37** on surface **35.** After oxide regions **42** have been formed, thin metal film contacts **38** are vacuum vapor deposited on the exposed portions of N regions **37.** Simultaneously with the formation of contacts **38** thin, metal film, annular contact **39** is vacuum vapor deposited on surface **35** in the region outside of cone **31***b*. After metal films **38** and **39** have been deposited, cones **31***a*, **31***b*, and **31***d* are suitably attached.

While metal is believed preferable in most instances for the absorber elements, it is to be understood that dielectric elements can also be utilized as elements for directing electromagnetic wave radiation to an optical to d.c. converter diode. The dielectric elements would preferably have the same configuration and dimensions as indicated supra while the optical to d.c. converter diode may be of a type described by Javin in the IEEE Spectrum, October, 1971, page 91.

While there have been described and illustrated several specific embodiments of the invention, it will be clear that variations in the details of the embodiments specifically illustrated and described may be made without departing from the true spirit and scope of the invention as defined in the appended claims.

I claim:

1. A device for converting electromagnetic wave energy having an electric field into electric power comprising a plurality of mutually insulated electromagnetic wave absorber elements each responsive to the electric field, adjacent ones of said elements converging toward each other in the direction of the wave propagation, each element including means for deriving a voltage replica of variations of the electric field intercepted by the element, adjacent ones of said elements being positioned relative to each other so that an electric field subsists between said adjacent elements, and means responsive to the voltage difference between the derived voltage replicas between two adjacent elements.

2. The device of claim **1** wherein each of the absorber elements is metallic.

3. The device of claim **1** where each of the absorber elements comprises a metallic surface and has a length in the direction of wave propagation several wavelengths of the impinging electromagnetic wave.

4. The device of claim **3** wherein the adjacent elements have substantially coplanar bases, and the spacing between the adjacent elements at the bases thereof is of the order of no more than a wavelength of the electromagnetic energy.

5. The device of claim **1** wherein the adjacent elements have substantially coplanar bases, and the spacing between the adjacent elements at the bases thereof is of the order of no more than a wavelength of the electromagnetic energy.

6. The device of claim **1** wherein the conversion means responsive to the voltage difference includes means for rectifying the voltage difference to derive a d.c. voltage.

7. A device for converting circularly polarized or randomly polarized electromagnetic wave energy having an electric field into electric power comprising a two-dimensional array of mutually insulated electromagnetic wave absorber elements each responsive to a component of the electric field, each elements converging toward each other in the direction of propagation of the wave and including means for deriving a voltage replica of variations of the electric field intercepted by the element, adjacent ones of said elements being positioned relative to each other so that an electric field subsists between said adjacent elements, and means responsive to the voltage difference between the voltage replicas derived between two adjacent elements, said pairs being spaced at right angles to each other in the array.

8. The device of claim **7** wherein each of the absorber elements is metallic.

9. The device of claim **7** where each of the absorber elements comprises a metallic surface and has a length in the direction of wave propagation several wavelengths of the electromagnetic wave.

10. The device of claim **9** wherein the adjacent elements have substantially co-planar bases and the spacing between the adjacent elements at the bases thereof of the order of one wavelength or less of the electromagnetic energy.

11. The device of claim **7** wherein the adjacent elements have substantially coplanar bases and the spacing between the adjacent elements at the bases thereof is of the order of one wavelength or less of the electromagnetic energy.

12. A device for converting solar, randomly polarized electromagnetic wave energy in the wave length band from approximately 0.3 to 1.1 microns into electric power comprising a dielectric substrate having a face substantially at right angles to the direction of propagation of the solar electromagnetic wave energy, a plurality of mutually insulated electromagnetic wave, metallic absorber elements mounted on said face, each of said elements including tapered portion extending away from the face in the direction of propagation of the wave energy, each of said elements having a decreasing cross-sectional area as the distance from the face increases and a length in the direction of propagation of the wave several wavelengths of the shortest wavelength of the spectrum, an integrated circuit diode in said substrate connected to be responsive to wave energy intercepted by alternately spaced ones of said

elements, a metallic film on said substrate ohmically connected to the remaining metallic elements, whereby a capacitor is formed in the substrate dielectric between adjacent ones of said metallic films.

13. The device of claim **12** wherein each of the elements includes a base with a symmetrical geometry in contact with said face, each element having a cross section parallel to the base similar to the base.

14. The device of claim **13** wherein said face has a square cross section.

15. The device of claim **13** wherein said face has a circular cross section.

16. The device of claim **13** wherein each of said elements is a frustum.

17. The device of claim **12** wherein the spacing between adjacent ones of said elements is of the order of one wavelength or less of the shortest wavelength of the spectrum.

18. The device of claim **12** wherein the several wavelengths are between 1.25 and 75.

19. A device for converting solar, randomly polarized electromagnetic wave energy in the wave length band from approximately 0.3 to 1.1 microns into electric power comprising a dielectric substrate having a face substantially at right angles to the direction of propagation of the solar electromagnetic wave energy, a plurality of mutually insulated electromagnetic wave, metallic absorber elements mounted on said face, each of said elements including a tapered portion extending away from the face in the direction of propagation of the wave energy, each of said elements having a decreasing cross-sectional area as the distance from the face increases, adjacent ones of said elements being spaced from each other by a distance on the order of a wavelength or less of said energy, an integrated circuit diode in said substrate connected to be responsive to wave energy intercepted by alternately spaced ones of said elements, a first metallic film on said substrate ohmically connected to one electrode of each of said diodes, a second metallic film on said substrate ohmically connected to the remaining metallic elements, said first and second films including load terminals whereby a capacitor is formed in the substrate dielectric between adjacent ones of said metallic films, and said load terminals.

(57) ABSTRACT

A system and device for harvesting various frequencies and polarizations of ambient radio frequency (RF) electromagnetic (EM) energy for making a passive sensor (tag) into an autonomous passive sensor (tag) adapted to collect and store data with time-stamping and some primitive computation when necessary even when an interrogating radio frequency identification (RFID) reader is not present (not transmitting). A specific source of ambient RF EM energy may include wireless fidelity (WiFi) and/or cellular telephone base stations. The system and device may also allow for the recharging of energy storage units in active and battery assisted passive (BAP) devices. The system could be a "smart building" that uses passive sensors with RF EM energy harvesting capability to sense environmental variables, security breaches, as well as information from "smart appliances" that can be used for a variety of controls and can be accessed locally or remotely over the Internet or cellular networks.

HARVESTING AMBIENT RADIO FREQUENCY ELECTROMAGNETIC ENERGY FOR POWERING WIRELESS ELECTRONIC DEVICES, SENSORS AND SENSOR NETWORKS AND APPLICATIONS THEREOF

CROSS REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional Patent Application No. 60/705,636 filed on Aug. 4, 2005, the contents of which in its entirety is herein incorporated by reference.

BACKGROUND

1. Technical Field

The embodiments herein generally relate to wireless technology, and, more particularly, to harvesting ambient radio frequency (RF) electromagnetic (EM) energy for supplying, storing, recharging or supplementing the energy necessary to power active or passive wireless electronic devices, sensors and sensor networks.

2. Description of the Related Art

The ability of actively powered, battery assisted passive (BAP) and passive wireless sensors to remotely acquire, store and/or transmit data may open up a wide variety of medical, diagnostic, quality control, safety, supply chain, logistic and security applications. For an individual, the ability to determine, prior to consumption, whether a food item contains harmful bacteria or ingredients to which the individual is allergic is highly desirable. From a population's perspective, recent national and international events have increased the need for personal or distributed systems that can monitor and detect continuously in real-time or at periodic or irregular intervals in time, chemical agents, biological agents, radiological agents and other hazards locally or over wide geographical areas.

Examples of personal handheld wireless devices that can address these issues are cellular telephones (cell phones), personal data assistants (PDAs) and portable computers or notebooks (PCs). These are pervasive electronic devices that are networked via the Internet or cellular telephone networks. Generally, the abovementioned consumer electronic devices all require local energy storage (batteries) to provide mobility and portability, and do so until their local source of energy is depleted.

A new class of sensors such as Electronic Product Code (EPC) and Radio Frequency Identification (RFID) tags that include sensing capabilities are emerging as a generally inexpensive and effective means of addressing many wireless sensor applications such as, but not exclusively, cold-supply chain, food safety, quality control, environmental safety, medical, diagnostic, electro-immunoassays, consumer goods as well as homeland security, property and personal security applications.

Purely passive sensors, when actively interrogated by an RF transceiver (reader), use this received source of EM energy to power themselves up, to acquire readings from their sensors and then rebroadcast or reflect their specific identification code and sensor readings back to the interrogator. BAP tags use their batteries to acquire and store or log data from one or more sensors, but typically do not use their batteries to enhance their RF communication abilities. Active sensors have their own built in power source that can be used to acquire and store sensor readings at any time as well as enhance the reception and transmission of RF communications. Generally, passive EPC and RFID tags equipped with one or more sensors will require a source of energy to measure and store their acquired information at times other than during active interrogation by a reader.

Because of the cost of the conventional sensors and sensor readers in particular, broad deployment of a sensor network over a large geographical area or widespread use by individuals is currently not particularly feasible. Generally, a considerable problem with large geographical deployment is that if the sensors are actively powered, their power sources need to be replaced when depleted, again adding to the cost. In addition, wear on sensors or sensor surfaces, generally requires sensors to be replaced on a regular basis further increasing the cost. In addition, imprecision in sensors generally requires cross validation to eliminate false positives, increasing the number of sensors that must be deployed for each application and thus also increasing the cost.

Accordingly, in view of the foregoing, there remains a need for low cost wireless sensors that can harvest ambient EM energy to power themselves up, acquire sensor data or recharge their power sources (batteries in the case of active sensors and batteries in BAP sensors).

SUMMARY

In view of the foregoing, the embodiments herein provide wireless RF addressable sensor network architectures for individuals, homes, industries, and homeland security where a wireless reader can supply RF power to and communicate with RF addressable tags that include sensors. Each active, BAP or passive tag can be equipped to harvest ambient EM energy from its environment allowing it to be autonomous: the tag can acquire and store data from its sensors independently of any particular reader event. The harvested ambient EM energy could, in addition, be used to transmit an alarm or "read me!" signal when a vital "sensor event" occurs, or to charge a battery on or near the tag. For example, the reader could be an RFID reader, a broadband wireless fidelity (WiFi) device, a cell phone, PDA, PC or a hybrid thereof comprising of a device adapted to read an RFID tag's unique identification and sensor information and bi-directionally communicate this information over the Internet or cellular telephone networks. The embodiments herein are also directed towards RF addressable tags with sensors that may be produced at costs lower than most types of active or passive tags conventionally available and furthers the state of the art by including ambient EM energy harvesting capabilities.

The RF addressable sensor tag combines RFID tag functionality with sensor functionality. The RF addressable sensor includes one or more antennas for communicating with the tag reader, one or more sensor elements, an RF power and communications interface, an RFID control module, and a sensor interface. The RFID control module includes logic to control RFID tag communications with an RFID tag reader. The RFID control module may also include logic and memory necessary to store and/or process the acquired sensor data.

The embodiments herein additionally furthers the current state of the art by adding an ambient EM energy harvesting sub-system to passive, BAP, or active wireless sensor tags. The harvested energy is used to provide power to the passive sensor or to provide power to the BAP or active sensor or for recharging an energy source on the active sensor tag or BAP sensor tag. This harvested energy is used by the sensor tag for: the facilitation of autonomous data collection and/or storage; the processing of acquired data; and the transmission of an alarm or "read-me!" signal when a vital sensor variable is above or below a critical threshold or vital sensor variables are above or below critical thresholds.

The embodiments herein are also adapted to identify WiFi and cellular base stations as sources of readily available, known frequency, ambient RF EM energy that can be harvested to provide energy to the sensor tag. The embodiments herein are also capable of identifying microwave band frequencies consistent with IEEE 521-1984 designations (Bands L, S, C, X, Ku, K, Ka, V, and W) as ambient RF EM energy that can be harvested to provide energy to the sensor tag.

In an instantiation of the embodiments herein, an RFID reader is used to communicate with nearby sensor tags that are being energized by harvested ambient RF EM energy supplied by a nearby WiFi router/transceiver or cellular base station. The WiFi router/transceiver or cellular base station not only supplies the ambient energy for the sensor tags, but also bi-directionally communicates and distributes the collected sensor tag data over the Internet or cellular telephone networks.

In an aspect of the embodiments herein, the RFID reader and WiFi router/transceiver are combined into a hybrid RFID-WiFi reader whereby the RFID reader sub-system communicates with nearby sensor tags that are being energized by harvested ambient RF EM energy supplied by the WiFi router/transceiver part of the hybrid RFID-WiFi reader. The WiFi router/transceiver part of the hybrid RFID-WiFi reader also facilitates the local and/or remote distribution of the collected sensor tag data over the Internet.

In another aspect of the embodiments herein, the RFID, WiFi router/transceiver, and cell phone technology are combined into a hybrid RFID-WiFi-cell phone reader whereby the RFID and/or WiFi reader sub-system communicates with nearby RFID sensor tags and the WiFi and cell phone subsystems facilitate local and remote access to the collected sensor tag data over the Internet or via the cellular telephone networks. The WiFi router/transceiver part of the hybrid RFID-WiFi-Cell phone reader is also the source of ambient energy available for harvesting by the sensor tags.

In another aspect of the embodiments herein, a source that radiates EM energy at a known frequency may be placed in the vicinity of the passive, BAP or active sensor tags for the sole purpose of supplying ambient RF EM energy at frequencies that these wireless sensors can harvest.

The energy harvesting system may include an antenna or an array of antennas to collect ambient EM energy having a single wavelength or a multitude of wavelengths of single polarization or arbitrary polarizations. In another aspect of the embodiments herein the energy harvesting antenna or antennas may be used to supplement the wireless tag's communication antenna or antennas. In another instantiation of the embodiments herein, the energy harvesting antenna or array of antennas connects to an impedance matching network and a rectifying and combining module before being fed to the power converting and/or conditioning module.

In yet another instantiation of the embodiments herein, the energy harvesting antenna or array of antennas may be designed to directly rectify the harvested energy (a rectenna or array of rectennas) and feed the rectified energy to an energy combining module that in turn feeds a power converting and/or conditioning module.

In another aspect of the embodiments herein, the energy harvesting power converting and/or conditioning module can supplement the wireless tag's RF transceiver power and thereby its communication capabilities. Furthermore, the embodiments herein preferably do not interfere with the communications between RFID readers and wireless RF addressable tags.

Generally, the embodiments provide a system comprising an ambient RF EM energy source; a sensor reader operatively connected to the ambient RF EM energy source; and a sensor in communication with the sensor reader, wherein the sensor comprises a control module comprising an energy harvesting controller; a tag module controlled by the control module; a sensor module controlled by the control module; an energy harvesting module controlled by the energy harvesting controller and adapted to wirelessly collect the ambient RF EM energy; and a power module adapted to provide a power supply for the control module, the power supply being generated by the collected ambient RF EM energy, wherein the energy harvesting controller is adapted to (i) assess power requirements of each of the tag and sensor modules, (ii) transfer power from the energy harvesting module to any of the tag and sensor modules, and (iii) charge a local energy storage device.

In one embodiment, the sensor further comprises an antenna module shared by the energy harvesting module and the tag module, wherein the antenna module comprises a rectification and impedance matching network; at least one RF pad operatively connected to the rectification and impedance matching network; and at least one antenna operatively connected to each of the at least one RF pad. In another embodiment, the tag module comprises a memory component; a RF communication interface operatively connected to the memory component; at least one RF pad operatively connected to the RF communication interface; and at least one antenna operatively connected to each of the at least one RF pad. The sensor module may comprise a memory component; a sensor interface and support sub-system operatively connected to the memory component; at least one sensor pad operatively connected to the sensor interface and support sub-system; and at least one antenna operatively connected to each of the at least one sensor pad. Alternatively, the sensor module comprises a memory component; a sensor interface and support sub-system operatively connected to the memory component; and at least one antenna operatively connected to sensor interface and support sub-system. Preferably, the control module further comprises a RFID tag controller; and a sensor processing controller operatively connected to the RFID tag controller.

In one embodiment, the energy harvesting module comprises an energy harvesting interface and support sub-system; at least one RF harvesting pad operatively connected to an energy harvesting interface and support sub-system; and at least one antenna operatively connected to each of the at least one RF harvesting pad. Alternatively, the energy harvesting module comprises an energy harvesting interface and support sub-system; at least one pair of RF harvesting pads operatively connected to the energy harvesting interface and support sub-system; and at least one rectenna operatively connected to each of the at least one pair RF harvesting pads. The energy harvesting interface and support sub-system may comprise a storage component; a power conditioner component operatively connected to the storage component; and a combiner operatively connected to the power conditioner, wherein the energy harvesting interface and support subsystem comprises a rectification and impedance matching network operatively connected to the combiner. Preferably, the power module comprises a power charger; a power source operatively connected to the power charger; and a voltage regulator operatively connected to the power source.

Additionally, the collected ambient RF EM energy enables the electronic device to be a fully autonomous data collector, alarm generator, event generator, data logger, and data processor independent of any other device. Moreover, the sensor reader may comprise any of a cell phone, a PDA, a PC reader, a RFID reader, a broadband WiFi device, and a combination thereof. Preferably, the power supply is generated only by the collected ambient RF EM energy. Furthermore, the sensor may be adapted to transmit a wireless signal to the sensor reader, and wherein the sensor reader is adapted to receive the transmitted wireless signal from the sensor. Also, the collected ambient RF EM energy facilitates transmission of the wireless signal when a selected sensor variable meets a predetermined threshold. In one embodiment, the ambient RF EM energy source comprises a WiFi router adapted to allow the sensor reader to communicate over the Internet.

Alternatively, the ambient RF EM energy source comprises a hybrid WiFi router transceiver adapted to allow the sensor reader to communicate over the Internet. In another embodiment, the sensor is a RF ambient EM energy harvesting sensor and is arranged with a plurality of other the sensors each adapted to collect data for climate control, security alarms, environmental alarms, and information gathering from other devices located within a communicable distance from the sensor, wherein all of the sensors are adapted to be any of locally and remotely monitored via any of the Internet and a cell phone network.

These and other aspects of the embodiments herein will be better appreciated and understood when considered in conjunction with the following description and the accompanying drawings. It should be understood, however, that the following descriptions, while indicating preferred embodiments and numerous specific details thereof, are given by way of illustration and not of limitation. Many changes and modifications may be made within the scope of the embodiments herein without departing from the spirit thereof, and the embodiments herein include all such modifications.

BRIEF DESCRIPTION OF THE DRAWINGS

The embodiments herein will be better understood from the following detailed description with reference to the drawings, in which:

FIG. **1** is a schematic diagram illustrating an example of ambient RF EM energy harvesting for gathering, accumulating, and storing energy and powering passive wireless sensors or sensor tags and/or recharging BAP and/or active wireless sensors or sensor tags all of which are equipped with ambient EM energy harvesting technology according to an embodiment herein;.

FIG. **2** is a schematic diagram illustrating the deployment of wireless addressable sensor tags with on-board EM energy harvesting technology in a home, business, office, warehouse, or building according to an embodiment herein;

FIG. **3**A is a schematic diagram illustrating an example of a WiFi wireless router/transceiver, connected to the Internet, bathing passive and/or BAP and/or active wireless sensor tags with energy at a known frequency or known frequencies according to an embodiment herein;

FIG. **3**B is a schematic diagram illustrating an example of a hybrid RFID-WiFi wireless router comprising an RFID tag reader module combined with a WiFi router/transceiver connected to the Internet according to an embodiment herein;

FIG. **3**C is a schematic diagram illustrating an example of a hybrid RFID-WiFi-cell phone wireless router comprising an RFID tag reader module, a WiFi router/transceiver module that facilitates connection to the Internet, and a cell phone module that facilitates connection to cellular telephone networks according to an embodiment herein;

FIG. **4**A is a schematic diagram illustrating an example of an RFID sensor tag equipped with an energy harvesting subsystem that initiates an alarm or "read me!" signal when a measured variable or combination of measured variables exceeds a predefined critical threshold according to an embodiment herein;

FIG. **4**B is a schematic diagram illustrating an example of an RFID sensor tag equipped with the energy harvesting sub-system logging (writing to memory) the sensed data according to an embodiment herein;

FIG. **5**A is a block diagram illustrating a passive wireless RF addressable tag module with a sensor module;

FIG. **5**B is a block diagram illustrating an active wireless RF addressable tag module with a sensor module;

FIG. **6** is a block diagram illustrating an EM energy harvesting sub-system architecture according to an embodiment herein;

FIG. **7**A is a block diagram illustrating a passive wireless RF addressable tag with a sensor module combined with an EM energy harvesting sub-system architecture according to an embodiment herein;

FIG. **7**B is a block diagram illustrating an active wireless RF addressable tag architecture with a sensor module combined with an illustrative EM energy harvesting sub-system architecture according to an embodiment herein;

FIG. **8** is a block diagram illustrating a passive wireless RF addressable tag architecture with a sensor module, an EM energy harvesting sub-system, and an antenna module that could be used for RF communication with a reader as well as to harvest ambient EM energy according to an embodiment herein;

FIG. **9**A is a block diagram illustrating an example of an EM energy harvesting architecture comprising an antenna or an array of antennas with associated rectification and matching networks according to an embodiment herein; and

FIG. **9**B is a block diagram illustrating an example of an EM energy harvesting architecture comprising a rectenna (rectifying antenna) or an array of rectennas with rectification and matching built into each rectenna according to an embodiment herein.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The embodiments herein and the various features and advantageous details thereof are explained more fully with reference to the non-limiting embodiments that are illustrated in the accompanying drawings and detailed in the following description. Descriptions of well-known components and processing techniques are omitted so as to not unnecessarily obscure the embodiments herein. The examples used herein are intended merely to facilitate an understanding of ways in which the embodiments herein may be practiced and to further enable those of skill in the art to practice the embodiments herein. Accordingly, the examples should not be construed as limiting the scope of the embodiments herein.

As mentioned, there remains a need for low cost wireless sensors that can harvest ambient EM energy to power themselves up, acquire sensor data or recharge their power sources (batteries in the case of active sensors and batteries in BAP sensors). The embodiments herein achieve this by providing a technique for harvesting ambient RF EM energy for supplying, storing, recharging or supplementing the energy necessary to power active, BAP or passive wireless electronic devices, sensors and sensor networks, allowing them to become autonomous "data loggers" and/or empowering them to transmit their unique identification and sensor information when a sensed variable or a combination of sensed variables exceeds a threshold and triggers a vital "sensor event".

More specifically, the embodiments provide a system and device for harvesting various frequencies and polarizations of ambient RF EM energy for making a passive sensor (tag) into an autonomous passive sensor (tag) adapted to collect and store data with time-stamping and some primitive computation when necessary even when an interrogating RFID reader is not present (not transmitting). A specific source of ambient RF EM energy may include WiFi. The system and device may also allow for the recharging of energy storage units in active and BAP devices. The system could be a "smart building" that uses passive sensors with RF EM energy harvesting capability to sense environmental variables, security breaches, as well as information from "smart appliances" that can be used for a variety of controls and can be accessed locally or remotely over the Internet or cellular telephone networks. Referring now to the drawings, and more particularly to FIGS. **1** through **9**B, where similar reference characters denote corresponding features consistently throughout the figures, there are shown preferred embodiments.

The embodiments herein relate to ambient EM energy harvesting for powering passive wireless sensors and for recharging energy storage devices on active or BAP wireless sensors. The RF frequency band from 3 KHz to 300 GHz, and a subset of this band, the Microwave Frequency Band from 1 GHz to 110 GHz (as designated in IEEE 521-1984) are identified as the most ubiquitous sources of ambient energy available for energy harvesting.

The embodiments herein furthers the current state of the art by focusing on RFID sensor tag technologies that may be purely passive (i.e., no on-board power supply but may have on-board energy storage devices) and/or active (i.e., having on-board energy storage as the power supply) and/or BAP (i.e., also having on-board energy storage as the power supply). The distinction between active and BAP wireless sensors is made here: an active tag uses its local power source to power up its sensors and boost its RF receive and transmit communications power while a BAP tag uses its local power source to power up and collect data from its sensors alone.

In particular IEEE standards 802.11a, 802.11b, and 802.11g and WiFi routers/transceivers used in homes, businesses, warehouses, stores and in towns or cities transmit a known wavelength (or frequency) in the S-band (2 GHz to 4 GHz) and the C-band (4 GHz to 8 GHz). This source of energy can be optimally harvested with a combination of appropriately designed antenna or antennas and rectenna or rectennas, impedance matching circuits, voltage regulation circuits and energy storage devices and can be used for supplying energy to wireless sensors, be they passive, BAP or active.

EM energy transmitted by cell phone towers (cellular base stations) is also designated as a ubiquitous source of energy of known wavelength (or frequencies in the 800 MHz to 1.9 GHz), and may likewise be optimally harvested and processed for supplying energy to wireless sensors, be they passive, BAP or active.

In addition a further improvement to the state of the art and provided by the embodiments herein is a hybrid RFID-WiFi transceiver that combines an RFID sensor tag reader and a WiFi router/transceiver into a device that can provide ambient EM energy to RFID sensor tags, read their unique identity and data from the tag and transmit this data over the Internet. The hybrid RFID-WiFi transceiver enables remote query of RFID sensor tags' identity and data via the Internet.

An additional improvement to the state of the art provided by the embodiments herein is a hybrid RFID-WiFi-cell phone transceiver that combines an RFID sensor tag reader, a WiFi router/transceiver, and a cell phone into a device that can provide ambient EM energy to RFID sensor tags, read their unique identity and data from the tag and transmit this data over the Internet and/or cellular telephone networks. The hybrid RFID-WiFi-cell phone transceiver enables remote query of RFID sensor tags' identity and data over the Internet as well as via cellular telephone networks.

The embodiments herein further improves upon the state of the art by making it possible for purely passive sensors to harvest available EM energy from their environment, and locally accumulate and store this energy so that passive tags become autonomous; i.e., they can log data and they can transmit an alarm or "read me!" signal to a nearby reader when a critical sensor event occurs or when a critical combination of sensor events occur or when a sensor level or combination of sensor levels has crossed a threshold.

FIG. **1** is an illustrative scenario of some of the forms of ambient EM energy that may be available for harvesting by passive RF addressable sensor tags **110** with energy harvesting capability. The ambient EM energy bathing the environment **115** in which the tags **110** are placed can come from a number of different sources including broadband WiFi routers/transceivers 120 (including but not limited to IEEE 802.1x, IEEE 802.15.4 "Zigbee®" electronic devices, Bluetooth® telecommunication equipment, HomeRF® computer hardware/software, HiperLAN/1 and HiperLAN/2), an EM transmitter **130** continuously or periodically radiating a known frequency (or frequencies), Microwave IEEE 521-1984 or cell phone base stations **140**, satellite transceivers **150**, wireless tag sensor readers **160**, and cell phones, PDAs or PCs **170**.

The energy that each of these sources contribute to the total amount of ambient EM energy available for harvesting by the antenna (not shown) of the tag **110**, $P_{RF}(t)$ **125**, **135**, **145**, **155**, **165**, **175** respectively, is a function of time, position/distance, frequency, solid angle and polarization state:

$$P_{RF}=\frac{1}{f_2-f_1}\int_{f_1}^{f_2}\int_0^{4\pi}\Phi(\Omega,f,t)A_{eff}(\Omega,f)d\Omega df$$

where Ω is the solid angle in steradians, $\Phi(\Omega f,t)$ is the time-varying frequency and angle-dependent incident power density and A_{eff} is the angle-, frequency-, and polarization-dependent effective area of the antenna.

The available power $P_{RF}(f_i)$ at any frequency f_i is an alternating current (ac) signal that must be converted to a direct current (dc) signal by a nonlinear device or rectifier (not shown) before being summed together with all other energy sources of different frequencies, $f_{1\ldots n}$, which have been similarly rectified. The dc power, P_{dc} at a single frequency, f_i is given by:

$$P_{dc}(f_i)=P_{RF}(t,f_i)n[P_{RF}(t,f_i),\beta]$$

where $\eta=P_{dc}/P_{RF}$ is the total received rectified and summed power conversion efficiency (including the loss due to reflected power), and $\beta(P_{dc},f_i,)$ represents the extent to which the rectifying device (not shown) and the antenna are impedance matched at the received dc power level, P_{dc} and frequency f_i.

The anticipated ambient power densities that can be harvested and converted to dc power at useful voltage levels is approximately in the range 10^{-1} mW/cm^2 (the FCC exposure limit for 880 MHz and 1990 MHz) to 10^{-6} mW/cm^2. One skilled in the art can optimize the harvested dc power, P_{dc} by appropriately adjusting the parameters A_{eff} and/or the parameters η and, β.

FIG. **2** is an illustrative example of a "smart home" 200 where RF addressable sensor tags **110** with energy harvesting capability are mounted on windows **210**, a door **220**, and in the attic **230**. Wired **270** or satellite transceiver **150** broadband Internet access is connected to a WiFi router **120** which bathes the smart house **200** in RF energy. Alternatively, an RF EM source **130** of known frequency continuously or periodically radiates energy specifically for the purpose of providing energy for the RF addressable sensor tags **110** with energy harvesting capability. An RFID tag reader **160** or a cell phone, PDA or PC **170** can read the unique identity and sensor data from each passive sensor tag **110**. The sensor tags **110** can be used to monitor environmental conditions such as temperature, humidity, carbon monoxide levels, radiation levels or smoke inside the house and the data read from the sensor tags **110** may be used to control HVAC systems or sound alarms when sensor thresholds are exceeded. The same sensor tags **110** can be used to detect unwanted intruders via vibration detectors, breakage detectors and open door detectors. Accordingly, the data from such sensors **110** can be used in a home security monitoring device. Similarly, addressable sensor tags **110** with energy harvesting capability can be placed on home appliances such as refrigerators, stoves, hot water heaters and gas/oil furnaces to monitor their operating state. Since the smart house **200** is connected to the Internet **270**, **150**, and/or via a cell phone **170**, all sensor data can be accessed locally and/or remotely over existing Internet and/or cellular telephone networks. Again, these sensors **110** harvest ambient energy from any or all of the available modes of RF EM energy bathing the house **200**. This energy could be used to power the passive sensor tags **110** or recharge batteries or other power sources associated with active or BAP tags **110**.

FIG. **3**A illustrates an example of a WiFi router/transceiver **120** connected to the Internet **270**, bathing passive, BAP or active wireless sensor tags **110** with energy at a known frequency **125**. This particular source of ambient energy supplies the passive sensor tag **110** with power or facilitates recharging batteries or other on-board or nearby energy storage devices. A single tag reader **160** (or a plurality of tag readers) is adapted to interrogate **330** each uniquely identifiable sensor tag **110** for information about its particular sensor tag reading(s) **320** and pass this information to the WiFi router/transceiver **120** via a direct connection **310** to make it locally or remotely accessible via the Internet and/or cell phone networks. This particular source of ambient energy can supply the passive sensor tag **110** equipped with energy harvesting capability with power for autonomous data collection and storage, or facilitate recharging batteries or other energy storage devices.

FIG. **3**B illustrates a hybrid RFID-WiFi wireless router **340** comprising an RFID tag reader module combined with a WiFi router/transceiver connected to the Internet **270**. This hybrid RFID-WiFi reader/module **340** provides a source of ambient energy **125** which the sensor tag **110** can harvest to supply itself with power to become an autonomous sensor **110** able to collect and save data as well as send out an alarm if its reading(s) has/have crossed a predefined threshold or a combination of predefined thresholds. The harvested energy can also facilitate recharging batteries or other energy storage devices associated with each tag **110**. The hybrid RFID-WiFi router/transceiver **340** periodically or sporadically interrogates **330** each uniquely identifiable sensor tag **110** for its data, and each uniquely identifiable sensor tag **110** rebroadcasts **320** its particular sensor(s) reading(s) back to the RFID-WiFi router/transceiver **340** which makes that data accessible over the Internet.

FIG. **3**C illustrates a hybrid RFID-WiFi-Cell phone router/transceiver **350** comprising an RFID tag reader module, a WiFi router/transceiver module and a cell phone module. This hybrid RFID-WiFi-Cell phone reader module **350** provides a source of ambient energy **125** which the sensor tag **110** can harvest to supply itself with power to become an autonomous sensor **110** able to collect and store data as well as send out an alarm if its reading(s) has/have crossed a predefined threshold or a combination of predefined thresholds. The harvested energy can also facilitate recharging batteries or other energy storage devices associated with each tag **110**. The hybrid RFID-WiFi-Cell phone router/transceiver **350** periodically or sporadically interrogates **330** each uniquely identifiable sensor tag **110** for its data, and each uniquely identifiable sensor tag **110** rebroadcasts **320** its particular sensor(s) reading(s) back to the hybrid RFID-WiFi-Cell phone router/transceiver **350** which is connected to the Internet **270** and makes that data accessible over the Internet as well as over cellular telephone networks.

FIG. **4**A illustrates an RFID temperature sensor tag **410** equipped with energy harvesting capability. Ambient EM energy **430** is harvested by the sensor tag **410**. This harvested energy is used by the tag **410** to continuously, periodically, or sporadically measure its sensor's value and compare that value with a pre-programmed threshold **470**. If this threshold is crossed, the tag **410** initiates and broadcasts an alarm or "read me!" signal **460** which is read by an RFID reader **160** or cell phone, PDA, or PC reader **170** along with its unique identification number. In this particular illustrative example the tag **410** senses temperature, but in general, the sensor or sensors of the tag **410** could measure a variety of environmental or physical variables. The unique identification and sensor data of the tag **410** can then be read by a standalone RFID reader **160** or by a cell phone, PDA, or PC reader **170**.

FIG. **4**B illustrates an RFID temperature sensor tag **410** equipped with energy harvesting capability that uses ambient EM energy **430** to provide a continuous, periodic, or sporadic source of power to the RFID temperature sensor tag **410**. The sensor tag **410** logs data to local memory **480** and can periodically or sporadically initiate and broadcast a signal **485**, which can be read by the RFID reader **160**. The RFID reader **160** can also periodically or sporadically initiate a read **490** of the unique identification and data of the tag **410**. In this particular illustrative example the tag **410** senses temperature, but in general, the sensor or sensors of the tag **410** could measure a variety of environmental or physical variables. The unique identification and sensor data of the tag **410** can then be read periodically or sporadically either when a sensor event initiates a "read me!" signal **485**, or when a standalone RFID reader **160** or a cell phone, PDA, or PC reader **170** initiates a read cycle **490**.

FIG. **5**A illustrates a passive wireless RF addressable sensor tag **500***a*, which may be used as a basis for designing the embodiments herein. The passive RFID tag **500***a* includes three main modules: the control module **510**, the tag module **540**, and the sensor module **520**. The control module **510** has an RFID tag controller **514** and a sensor processing controller **512** that can communicate with each other. The RFID tag controller **514** communicates with and controls the tag module **540**. The tag module **540** has on-board memory **542** and an RF communication interface **546**. The memory **542** holds the unique identification number and additional information **544** associated with that particular sensor tag **500***a*. The RF communication interface **546** has a voltage regulator **548** and a communication interface **550**. The RF communication interface **546** connects to a single antenna or a multitude of antennas **556** through an RF pad or a multitude of RF pads **554**. The sensor module **520** has its own memory **522** and a sensor interface and support sub-system **526**. The memory **522** stores the sensor data table **524** that include sensor calibration parameters, lookup tables as well as data collected from the sensor or sensors of the sensor tag **500***a*. The sensor interface and support sub-system **526** has a voltage and/or current reference generator **528**, an integrated temperature sensor **530** and an analog to digital converter **532**. An external sensor or a multitude of external sensors **536** are connected to the sensor interface and support sub-system **526** via a sensor pad or a multitude of sensor pads **534**.

FIG. **5**B illustrates an active or BAP wireless RF addressable sensor tag **500***b*, which may be used as a basis for designing the embodiments herein. In addition to all of the components described with FIG. **5**A above, there is also an active source module **560** which communicates with the control module **510**. The active source module **560** includes a power source **564** which could be replaceable and/or rechargeable, and voltage regulation circuitry **562** which regulates the voltage and/or current necessary to recharge the power source **564** and supply power to the remainder of the sensor tag **500***b*.

FIG. **6** is an illustrative example of a block diagram of the embodiments herein as it relates to the harvesting of ambient EM energy for supplying, storing, recharging, or supplementing the energy necessary to power active, BAP or passive wireless electronic devices, sensors and sensor networks. The EM energy harvesting sub-system architecture **600** comprises a single antenna **650**, rectifier and matching network **638** or an array of antennas **650**, rectifiers and matching networks **638**, a combiner **636**, a power conditioner **634**, and an energy storage device **632**. The energy harvesting controller **610** communicates bi-directionally with the energy harvesting module **620** and RFID tag controller **514**, wherein both the energy harvesting controller **610** and energy harvesting module **620** may or may not be integrated into an RFID sensor chip (not shown), depending on the particular application. The energy harvesting controller **610** sporadically, periodically or continuously controls and monitors the state of the energy harvesting module **620**. The energy harvesting module **620** includes an energy harvesting interface and support sub-system **630** that connects to an external energy harvesting antenna or multitude of external energy harvesting antennas **650** through an RFh (RF harvesting) pad or a multitude of RFh pads **640**.

The antenna or multitude of antennas **650** may be designed to collect ambient EM energy at either a single frequency f_1, a range of frequencies f_i, i=1, 2, 3 . . . N, or a specific set of frequencies, for example $f_{\{i,j,k\}l}$={13.56 MHz, 438 MHz, 928 MHz, 2.54 GHz}. Moreover, the polarization state of the energy within the aperture of a single energy harvesting antenna or a multitude of energy harvesting antennas **650** can be arbitrary. Furthermore, the aperture or effective area A_{eff} of an energy harvesting antenna or multitude of energy harvesting antennas **650** can be optimized for a wavelength, and/or a range or set of wavelengths of the received EM energy, and can be readily accomplished by those skilled in the art.

The EM energy harvested by an energy harvesting antenna or a multitude of energy harvesting antennas **650** presents an ac signal or a multitude of ac signals to the rectification and matching network **638**. The matching network **638** is preferably designed to optimally match the frequency, polarization state and signal strength (power) dependence $\beta(P_{dc}, f_i)$ of the output impedance of the harvesting antenna(s) **650** and the input impedance of the rectification element or elements **638** to ensure maximum power transfer or harvesting efficiency. The rectifier or rectifiers **638** convert the ac signal(s) into a dc or voltage signal(s).

The combiner **636** takes its input from the output of the rectification and matching network **638** and combines the currents or voltages in any combination of series or parallel connections in order to provide the necessary quantity of dc power for passive, BAP, or active sensor tag operation. The conditioner **634** takes the dc power from the combiner **636** and converts this dc power into a specified voltage level and/or current level with efficiency η by using circuit techniques known by those skilled in the art. The voltage and/or current level may be determined by the requirements of the local energy storage device **632** and/or the active source module **560**. The storage device **632** acts as local storage and may be implemented using any or a combination of capacitors, supercapacitors, plastic batteries, polymer batteries, Li-Ion batteries, or any rechargeable energy storing technology that can be integrated within the energy harvesting module **620**.

FIG. **7**A is an illustrative block diagram of an instantiation of a passive sensor tag **110***a* that includes a control module **710**, a tag module **540**, a sensor module **520**, and an energy harvesting module **620**. The energy harvesting controller **610** is shown here as being part of the control module **710** and communicates with the RFID tag controller **514** and the sensor processing controller **512**. The energy harvesting controller **610** is responsible for assessing the power needs of the tag module **540** and the sensor module **520** and can divert power from its storage element **632** to the tag module **540** and the sensor module **520** as necessary.

FIG. **7**B is an illustrative block diagram of an instantiation of a BAP or active sensor tag **110***b* that includes the energy harvesting module **620**. The difference between this sensor tag **110***b* of FIG. **7**B and sensor tag **110***a* of FIG. **7**A is the addition of the power module **720** whose purpose is to control and distribute power to the control module **730**, the tag module **540**, and the sensor module **520** in a BAP or active sensor tag **110***b*. The power module **720** includes, but is not limited to, a charger **725**, a power source **564**, and voltage regulation **562**.

The charger **725** controls the continuous, periodic, or sporadic charging of energy storage devices, in particular the power source **564** which may be a capacitor, supercapacitor, plastic battery, polymer battery, Li-Ion batteries, or any rechargeable energy storage technology. The voltage regulation sub-system **562** regulates the voltage and/or current that is needed to charge/recharge the power source **564** or divert power to the tag module **540** and/or the sensor module **520** as determined by the control module **730**.

FIG. **8** is a block diagram of another illustrative example of a sensor tag **110***c*with EM energy harvesting capability. As with the sensor tag **110***a* of FIG. **7**A and sensor tag **110***b* of FIG. **7**B, the sensor tag **110***c* of FIG. **8** comprises a control module **730**, a sensor module **520**, a tag module **830**, an energy harvesting module **810**, and an antenna module **840**. The tag module **830** differs from the tag module **540** of FIGS. **5**A, **5**B, **7**A, and **7**B in that there are no RF pads **554** and no antennas **556**. The remaining functionality of the tag module **830** is the same as described above.

Likewise, the energy harvesting module **810** differs from the energy harvesting module **620** of FIGS. **6**, **7**A, and **7**B in that there are no RF pads **554** and no RF antenna **556**, nor are there RFh pads **640** or energy harvesting antennas **650** associated with this module **810**. The remaining components, storage **632**, conditioner **634**, and combiner **636** have the same functionality as described above.

The antenna module **840** serves both the tag module **830** and the energy harvesting module **810**. An antenna or a multitude of antennas **846** are used for both RF EM energy harvesting and for bidirectional RF communications with an RFID, hybrid RFID-WiFi or hybrid RFID-WiFi-Cell phone reader. The antenna or antennas are designed to optimize RFID read range as well as to optimize A_{eff}. Each antenna **846** is connected via an RF pad **844** to the rectification and matching network **842**.

The rectification and matching network **842** is used to match the impedance of the antenna(s) **846** to that of the rectifier(s) as described above. In the context of FIG. **8**, the rectification and matching network **842** includes the rectifier(s). Moreover, those skilled in the art would readily understand that diodes, transmission lines, microstrip elements, and surface mount components could be further included in the rectification and matching network **842** in order to provide the rectifier(s). Since this network **842** also allows RF communications to occur, frequencies corresponding to those used by the RFID, RFID-WiFi, or RFID-WiFi-Cell phone reader (not shown in FIG. **8**) are preferably isolated and directed to the communication interface **550** on the tag module **830**. The harvested EM energy, once rectified, is sent first to the combiner **636**, then to the conditioner **634**, and finally to storage **632** as described above.

FIG. **9**A is an illustrative example of a block diagram of one of many possible designs for an EM RF energy harvesting antenna array module **910** in accordance with the embodiments herein, with the functionality of the various components included therein as previously described above. FIG. **9**B is an illustrative example of a block diagram of an alternate method for harvesting EM RF energy. In this aspect of the embodiments herein, an EM RF energy harvesting rectenna array module **950** is provided as a possibly more efficient way to harvest ambient EM RF energy.

In FIG. **9**B, an array of rectennas **970**, $\text{Rectenna}_1, \ldots, \text{Rectenna}_n$, each comprise a pair of antennas **982**, **984**, optimized to collect a broad range of RF frequencies having time-varying polarization states, directly integrated with an impedance matched rectifier **980**. Each rectenna **970** could be made up of two interdigitated antennas, one with a clockwise winding **982**, the other with a counterclockwise winding **984**, with the rectifier **980** connected between the two inner ports of the antennas. The rectified signals are collected from the two outermost ports of the rectenna **970** and connected to pads $\text{RHh}_1, \ldots, \text{RFh}_n$, **960**.

The techniques provided by the embodiments herein may be implemented on an integrated circuit (IC) chip or using printable electronic technologies (not shown). The chip or printable electronic circuit design is created in a graphical computer programming language, and stored in a computer storage medium (such as a disk, tape, physical hard drive, or virtual hard drive such as in a storage access network). If the designer does not fabricate chips or printable electronic circuits or the photolithographic masks used to fabricate chips or printable electronic circuits, the designer transmits the resulting design by physical means (e.g., by providing a copy of the storage medium storing the design) or electronically (e.g., through the Internet) to such entities, directly or indirectly. The stored design is then converted into the appropriate format (e.g., GDSII or CIF) for the fabrication of photolithographic masks, which typically include multiple copies of the chip design in question that are to be formed on a wafer or printed on a suitable substrate. The photolithographic masks are utilized to define areas of the wafer or printable electronic circuits (and/or the layers thereon) to be etched or otherwise processed or printed.

The resulting integrated circuit chips or printable electronic circuits can be distributed by the fabricator in raw wafer form (that is, as a single wafer that has multiple unpackaged chips), as a bare die, or in a packaged form or as individual printed circuits or in a sheet or roll of printed circuits. In the latter case the chip is mounted in a single chip package (such as a plastic carrier, with leads that are affixed to a motherboard or other higher level carrier) or in a multichip package (such as a ceramic carrier that has either or both surface interconnections or buried interconnections). In any case the chip might then be integrated with other chips, discrete circuit elements, and/or other signal processing devices as part of either (a) an intermediate product, such as a mother or daughter-board, or (b) an end product. The end product can be any product that includes integrated circuit chip or chips and/or printed circuits, ranging from toys and other low-end applications to advanced computer products having a display, a keyboard or other input device, and a central processor.

Harvesting ambient EM energy would transform a purely passive sensor into an autonomous sensor **110***a*, **110***b*, **111***c* capable of periodic or sporadic sensor data acquisition, data logging and storage at times other than when being actively interrogated by a reader **160** as well as providing the necessary energy to either autonomously transmit a notable "sensor event", broadcast an alarm or "read me!" signal **460**, **485**, **490** when a threshold of the sensor **110***a*, **110***b*, **110***c* has been exceeded or when a combination of various thresholds of the sensor **110***a*, **110***b*, **110***c* have been exceeded.

The combination of passive and/or BAP and/or active wireless sensors **110***a*, **110***b*, **110***c* having ambient EM energy harvesting capabilities and wireless communication capabilities as provided by the embodiments herein provide a new low cost means for remotely sensing the environment, monitoring the state of a home, buildings, structures, goods and devices as well as remote and local personal/patient monitoring, medical diagnostic and medical care solutions.

Cell phones, PDAs and PCs **170** are pervasive electronic devices that are already networked via the Internet. A combination or integration of RFID readers, WiFi technologies and/or cell phone technologies into a hybrid reader that transparently communicates with RFID sensor tags, the Internet and cell phone networks would facilitate the widespread deployment and usage of passive sensor tags equipped with EM energy harvesting technology.

Broadband wireless communications networks such as WiFi (including WiMax™ telecommunication equipment and WiBro™ telecommunication equipment and any combination of IEEE 802.1x (where x is used to convey any or all of the following: 1a, 1b, 1g, 5 or 6), IEEE 802.15.4 "Zigbee®" electronic devices, Bluetooth® telecommunication equipment, HomeRF® computer hardware/software, HiperLAN/1 and HiperLAN/2) are being widely deployed in offices, factories, warehouses, stores, homes, communities, and cities. With long read ranges (up to several hundred feet), RFID tags and RFID readers can benefit from aspects of the embodiments herein by: using RFID and/or WiFi for short range communication between a tag reader and wireless sensor tags; using the WiFi and/or the cellular network infrastructure to communicate the acquired sensor tag data over the Internet or cellular telephone networks (bi-directionally); and using WiFi routers/transceivers or cellular base stations as a source of ambient EM energy, with known frequency, that can be optimally harvested to provide energy to inexpensive passive (BAP and/or active tags with rechargeable energy sources) sensor tags.

Generally, the embodiments herein provide a technique for harvesting ambient RF EM energy for supplying, storing, recharging or supplementing the energy necessary to power active, BAP or passive wireless electronic devices, sensors and sensor networks, allowing them to become autonomous "data loggers" and/or empowering them to transmit their unique identification and sensor information when a sensed variable exceeds a threshold and triggers a vital "sensor event". The data gathered by these autonomous data loggers can also be transparently read at any time by a variety of reader technologies such as RFID readers, cell phones, personal data assistants, personal computers, WiFi, WiMax™telecommunication equipment and WiBro™ telecommunication equipment, including IEEE 802.1x (where x is used to convey any or all of the following: 1a, 1b, 1g, 5, and 6), "Zigbee®" electronic devices, Bluetooth® telecommunication equipment, HomeRF® computer hardware/software, HiperLAN/1and HiperLAN/2 and any hybrid combinations thereof. The embodiments herein also provide a hybrid RFID-WiFi reader/transceiver **340** and a hybrid RFID-WiFi-cell phone reader/transceiver **350**. The RFID reader module communicates with RFID tags, the WiFi module supplies ambient energy which the passive sensor tags are equipped to harvest and provides connectivity to the Internet and may also read WiFi sensor tags, and the cell phone module provides connectivity to cellular telephone networks.

The foregoing description of the specific embodiments will so fully reveal the general nature of the embodiments herein that others can, by applying current knowledge, readily modify and/or adapt for various applications such specific embodiments without departing from the generic concept, and, therefore, such adaptations and modifications should and are intended to be comprehended within the meaning and range of equivalents of the disclosed embodiments. It is to be understood that the phraseology or terminology employed herein is for the purpose of description and not of limitation. Therefore, while the embodiments herein have been described in terms of preferred embodiments, those skilled in the art will recognize that the embodiments herein can be practiced with modification within the spirit and scope of the appended claims.

What is claimed is:

1. An electronic device comprising:

a control module comprising an energy harvesting controller;

a tag module controlled by said control module;

a sensor module controlled by said control module;

an energy harvesting module controlled by said energy harvesting controller and adapted to wirelessly collect ambient radio frequency (RF) electromagnetic (EM) energy; and

a power module adapted to provide a power supply for said control module, said power supply being generated by the collected ambient RF EM energy,

wherein said energy harvesting controller is adapted to (i) assess power requirements of each of the tag and sensor modules, (ii) transfer power from said energy harvesting module to any of said tag and sensor modules, and (iii) charge a local energy storage device.

2. The electronic device of claim **1**, further comprising an antenna module shared by said energy harvesting module and said tag module.

3. The electronic device of claim **2**, wherein said antenna module comprises:

a rectification and impedance matching network;

at least one RF pad operatively connected to said rectification and impedance matching network; and

at least one antenna operatively connected to each of said at least one RF pad.

4. The electronic device of claim **1**, wherein said tag module comprises:

a memory component;

a RF communication interface operatively connected to said memory component;

at least one RF pad operatively connected to said RF communication interface; and

at least one antenna operatively connected to each of said at least one RF pad.

5. The electronic device of claim **1**, wherein said sensor module comprises:

a memory component;

a sensor interface and support sub-system operatively connected to said memory component;

at least one sensor pad operatively connected to said sensor interface and support sub-system; and

at least one antenna operatively connected to each of said at least one sensor pad.

6. The electronic device of claim **1**, wherein said sensor module comprises:

a memory component;

a sensor interface and support sub-system operatively connected to said memory component; and

at least one antenna operatively connected to sensor interface and support sub-system.

7. The electronic device of claim **1**, wherein said control module further comprises:

a radio frequency identification (RFID) tag controller; and

a sensor processing controller operatively connected to said RFID tag controller.

8. The electronic device of claim **1**, wherein said energy harvesting module comprises:

an energy harvesting interface and support sub-system;

at least one RF harvesting pad operatively connected to an energy harvesting interface and support sub-system; and

at least one antenna operatively connected to each of said at least one RF harvesting pad.

9. The electronic device of claim **1**, wherein said energy harvesting module comprises:

an energy harvesting interface and support sub-system;

at least one pair of RF harvesting pads operatively connected to said energy harvesting interface and support sub-system; and

at least one rectenna operatively connected to each of said at least one pair RF harvesting pads.

10. The electronic device of claim **9**, wherein said energy harvesting interface and support sub-system comprises:

a storage component;

a power conditioner component operatively connected to said storage component; and

a combiner operatively connected to said power conditioner.

11. The electronic device of claim **10**, wherein said energy harvesting interface and support sub-system comprises a rectification and impedance matching network operatively connected to said combiner.

12. The electronic device of claim **1**, wherein said power module comprises:

a power charger;

a power source operatively connected to said power charger; and

a voltage regulator operatively connected to said power source.

13. The electronic device of claim **1**, wherein said collected ambient RF EM energy enables said electronic device to be a fully autonomous data collector, alarm generator, event generator, data logger, and data processor independent of any other device.

14. The electronic device of claim **1**, wherein said power supply is generated only by said collected ambient RF EM energy.

15. A system comprising:

an ambient radio frequency (RF) electromagnetic (EM) energy source;

a sensor reader operatively connected to said ambient RF EM energy source; and

a sensor in communication with said sensor reader, said sensor comprising:

a control module comprising an energy harvesting controller;

a tag module controlled by said control module;

a sensor module controlled by said control module;

an energy harvesting module controlled by said energy harvesting controller and adapted to wirelessly collect said ambient RF EM energy; and

a power module adapted to provide a power supply for said control module, said power supply being generated by the collected ambient RF EM energy,

wherein said energy harvesting controller is adapted to (i) assess power requirements of each of the tag and sensor modules, (ii) transfer power from said energy harvesting module to any of said tag and sensor modules, and (iii) charge a local energy storage device.

16. The system of claim **15**, wherein said sensor further comprises an antenna module shared by said energy harvesting module and said tag module.

17. The system of claim **16**, wherein said antenna module comprises:

a rectification and impedance matching network;

at least one RF pad operatively connected to said rectification and impedance matching network; and

at least one antenna operatively connected to each of said at least one RF pad.

18. The system of claim **15**, wherein said tag module comprises:

a memory component;

a RF communication interface operatively connected to said memory component;

at least one RF pad operatively connected to said RF communication interface; and

at least one antenna operatively connected to each of said at least one RF pad.

19. The system of claim **15**, wherein said sensor module comprises:

a memory component;

a sensor interface and support sub-system operatively connected to said memory component;

at least one sensor pad operatively connected to said sensor interface and support sub-system; and

at least one antenna operatively connected to each of said at least one sensor pad.

20. The system of claim **15**, wherein said sensor module comprises:

a memory component;

a sensor interface and support sub-system operatively connected to said memory component; and

at least one antenna operatively connected to sensor interface and support sub-system.

21. The system of claim **15**, wherein said control module further comprises:

a radio frequency identification (RFID) tag controller; and

a sensor processing controller operatively connected to said RFID tag controller.

22. The system of claim **15**, wherein said energy harvesting module comprises:

an energy harvesting interface and support sub-system;

at least one RF harvesting pad operatively connected to an energy harvesting interface and support sub-system; and

at least one antenna operatively connected to each of said at least one RF harvesting pad.

23. The system of claim **15**, wherein said energy harvesting module comprises:

an energy harvesting interface and support sub-system;

at least one pair of RF harvesting pads operatively connected to said energy harvesting interface and support sub-system; and

at least one rectenna operatively connected to each of said at least one pair RF harvesting pads.

24. The system of claim **15**, wherein said energy harvesting interface and support sub-system comprises:

a storage component;

a power conditioner component operatively connected to said storage component; and

a combiner operatively connected to said power conditioner.

25. The system of claim **24**, wherein said energy harvesting interface and support sub-system comprises a rectification and impedance matching network operatively connected to said combiner.

26. The system of claim **15**, wherein said power module comprises:

a power charger;

a power source operatively connected to said power charger; and

a voltage regulator operatively connected to said power source.

27. The system of claim **15**, wherein said collected ambient RF EM energy enables said electronic device to be a fully autonomous data collector, alarm generator, event generator, data logger, and data processor independent of any other device.

28. The system of claim **15**, wherein said sensor reader comprises any of a cell phone, a personal display assistant (PDA), a personal computer (PC) reader, a radio frequency identification (RFID) reader, a broadband wireless fidelity (WiFi) device, and a combination thereof.

29. The system of claim **15**, wherein said power supply is generated only by said collected ambient RF EM energy.

30. The system of claim **15**, wherein said sensor is adapted to transmit a wireless signal to said sensor reader, and wherein said sensor reader is adapted to receive the transmitted wireless signal from said sensor.

31. The system of claim **15**, wherein said collected ambient RF EM energy facilitates transmission of said wireless signal when a selected sensor variable meets a predetermined threshold.

32. The system of claim **15**, wherein said ambient RF EM energy source comprises a wireless fidelity (WiFi) router adapted to allow said sensor reader to communicate over the Internet.

33. The system of claim **15**, wherein said ambient RF EM energy source comprises a hybrid wireless fidelity (WiFi) router transceiver adapted to allow said sensor reader to communicate over the Internet.

34. The system of claim **15**, wherein said sensor is a RF ambient EM energy harvesting sensor and is arranged with a plurality of other said sensors each adapted to collect data for climate control, security alarms, environmental alarms, and information gathering from other devices located within a communicable distance from said sensor, wherein all of said sensors are adapted to be any of locally and remotely monitored via any of the Internet and a cell phone network.

35. A device comprising:

a control module comprising:

an energy harvesting controller;

a radio frequency identification (RFID) tag controller operatively connected to said energy harvesting controller; and

a sensor processing controller operatively connected to said RFID tag controller;

a tag module controlled by said control module;

a sensor module controlled by said control module; and

an energy harvesting module directly connected to said control module and controlled by said energy harvesting controller, wherein said energy harvesting module is adapted to wirelessly collect, process, and store ambient radio frequency (RF) electromagnetic (EM) energy,

wherein said energy harvesting controller is adapted to (i) assess power requirements of each of the tag and sensor modules, (ii) transfer power from said energy harvesting module to any of said tag and sensor modules, and (iii) charge a local energy storage device, and

wherein power for operation of said control module, said tag module, said sensor module, and said energy harvesting module is generated only by the collected ambient RF EM energy.

(57) ABSTRACT

A radio frequency energy harvester harvests RF energy from the environment. The energy harvester may include a local power source. The energy harvester may have an associated crystal radio antenna that harvests AM radio waves ubiquitously. The radio frequency energy harvested may be stored via a super capacitor. The stored energy may power a self-contained processing unit directly when the level of the energy harvested remains above a threshold level. However, if the energy harvested drops below the threshold level, the processing unit, which may include a radio, may switch to the local power source and/or a low power mode of operation. The low power mode of operation may reduce the amount of processing and/or transmitting by the radio. The processing unit may be part of a network of radios. The energy harvester may supply energy for a variety of applications, including building automation, industrial automation, power generation, and healthcare.

PASSIVE RF ENERGY HARVESTING SCHEME FOR WIRELESS SENSOR

PRIORITY AND CROSS-REFERENCE TO RELATED APPLICATION

This application claims priority under 35 U.S.C. §119(e) to provisional application Ser. No. 60/744,028, filed on Mar. 31, 2006, which is incorporated by reference in its entirety herein.

BACKGROUND

The present embodiments relate generally to harvesting environmental energy. More particularly, the present embodiments relate to harvesting energy from radio frequency (RF) signals to power a sensor node and/or wireless radio.

Wireless sensor networks (WSNs) of so-called "smart" sensors can be used in remote monitoring and control applications. However, in almost all applications that involve WSNs, there is a trade off between the need to sense and communicate useful information and the requirement to do so in an energy efficient manner. A WSN, once deployed, may be intended to work for long periods of time with only minimal human intervention. For instance, remote monitoring applications may include individual sensor nodes, numbering into the hundreds or even thousands, that each run on a limited supply of energy, such as a battery. As a result, with conventional sensor nodes, excessive on-board processing and, perhaps more importantly, frequent invocation of the sensor node's radio may rapidly deplete the on-board energy source. Therefore, there is a need to develop sensor network protocols and algorithms with energy-efficient and self-organizing capabilities.

Additionally, replacing depleted batteries may be inefficient or impractical. A network may include a large number of individual sensor nodes that may be difficult to access due to being implanted within a wall, a ceiling, a larger device, or a patient. Accordingly, there is also a need for novel energy harvesting schemes operable to power wireless sensor nodes, as well as automatically replenish on-board energy storage units.

BRIEF SUMMARY

By way of introduction, the embodiments described below include methods, processes, apparatuses, instructions, or systems for harvesting energy from freely available radio frequency (RF) signals. The energy harvested may power processing units, such as self-contained processing units or sensor nodes. A "passive RF energy harvesting system," or "harvesting system," may be connected to a processing unit having a processor and delivers power supply to the processing unit. Each harvesting system may be associated with a crystal radio receiver and/or an all pass or band pass filter operable to harvest energy from all radio frequency bands simultaneously or ubiquitously. As a result, more of the available RF energy may be harvested from the existing electromagnetic signals. The harvesting is ubiquitous since no tuning is required if the harvester is moved from place to place. Most of the RF energy scavenged may be harvested from amplitude modulated (AM) radio signals. The harvesting system may have a super capacitor that temporarily stores the RF energy captured. If the level of RF energy being harvested falls below a threshold level, an interrupt signal may be generated that directs the processing unit to conserve energy. For

instance, the processing unit may limit on-board processing or reduce the number and/or strength of signals transmitted via a wireless radio, or both.

In a first aspect, a method harvests passive radio frequency energy. The method includes harvesting radio frequency energy using a crystal receiver. The method also includes powering a processing unit directly from the radio frequency energy being harvested when the radio frequency energy being harvested or an associated signal is approximately equal to or above a threshold level, and alternatively powering the processing unit from an on-board power source when the radio frequency energy being harvested or the associated signal is below the threshold level.

In a second aspect, a method harvests passive radio frequency energy. The method includes harvesting radio frequency energy via a crystal receiver and storing the radio frequency energy harvested on a super capacitor for subsequent use.

In a third aspect, a system harvests passive radio frequency energy. The system includes a network of radios within a building operable to direct the operation of building equipment to control a building environment of a building and at least one radio within the network being a sensor node operable to harvest radio frequency energy via a crystal receiver, the radio frequency energy harvested being used to power the sensor node.

In a fourth aspect, a computer-readable medium having instructions executable on a computer stored thereon is described. The instructions include monitoring for an interrupt signal that is triggered when the radio frequency energy being harvested via a crystal receiver falls below certain threshold, the radio frequency energy being used to at least partially power a sensor node or charge the battery on the harvesting system. The instructions also include automatically reducing the amount of power being expended by the sensor node if the interrupt signal is detected.

The present invention is defined by the claims herein. Nothing in this section should be taken as a limitation on those claims. Further aspects and advantages of the invention are discussed below in conjunction with the preferred embodiments and may be later claimed independently or in combination.

BRIEF DESCRIPTION OF THE DRAWINGS

The components in the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention.

FIGS. **1** and **1***a* are system block diagrams of an exemplary passive RF energy harvesting systems;

FIGS. **2** and **2***a* are schematics of additional exemplary passive RF energy harvesting systems;

FIG. **3** is a schematic of an exemplary network of sensor nodes;

FIG. **5** is a top plan view of an exemplary network of sensor nodes within a building;

FIG. **6** illustrates an exemplary method of harvesting radio frequency energy;

FIG. **7** illustrates an exemplary interrupt handling method; and

FIGS. **8** and **9** illustrate exemplary antennas.

DETAILED DESCRIPTION OF THE DRAWINGS AND PRESENTLY PREFERRED EMBODIMENTS

The present embodiments are directed toward methods, processes, apparatuses, instructions, or systems for harvest-

ing freely available radio frequency (RF) energy from the environment, such as signals generated from amplitude modulated (AM) and frequency modulated (FM) radio stations. The RF energy harvested is used to power a "sensor node." The sensor node may include a processor, a sensor, an actuator, a wireless radio, and/or other components. The sensor node may be part of a network of radios in direct or indirect communication with one another, such as a wireless sensor network (WSN).

The sensor node may have an associated crystal radio receiver. The crystal radio receiver may operate as an all pass filter to harvest energy from all radio frequency bands simultaneously or ubiquitously. As such, more of the available RF energy may be captured for the given electromagnetic signals being received by the sensor node at a specific time.

The energy harvesting system may have an associated super capacitor that temporarily stores the RF energy received or a related signal, such as a voltage, a current, or other electrical parameter or signal associated with the RF energy harvested. In one embodiment, if a voltage associated with the RF energy being harvested falls below a given threshold, an interrupt signal may be generated that directs the sensor node to switch to a "low-power" mode to conserve energy. In low-power mode, the sensor node may reduce the amount of processing that an on-board processor performs. Alternatively or additionally, in low-power mode, the operation of an on-board wireless radio or transmitter may be altered and/or limited. For example, the wake-up period of the sensor nodes may be increased for energy saving purposes. Other manners of reduced sensor node operation may be employed to conserve energy being expended by the sensor node.

I. Crystal Radio Receivers

Generally, the embodiments discussed herein provide energy harvesting or scavenging for sensor nodes and/or wireless sensor networks (WSNs). In particular, AM RF signals may be harvested via crystal radio receivers to provide the primary, or even sole, source of power for the sensor nodes. Other crystal receivers may be used.

Crystal radios were popular by the 1950's, but are now almost obsolete. One of the key features of crystal radios is that they do not require batteries. The earplugs and/or speakers of a crystal radio may be powered solely by amplitude modulated (AM) radio signals. The crystal radio may employ a piezo-electric crystal, dielectric disk, oscillating crystal, or another type of crystal. The crystal may oscillate or vibrate due to the radio frequency signals being received. Exemplary crystal radio receivers are disclosed by U.S. Pat. Nos. 2,554,270, 2,805,332, 3,327,222, and 3,996,522, which are all incorporated herein by reference in their entireties. Other crystal radio receivers may be used.

The crystal radio technology may be used in new applications due to the advancement of semi-conductors and reduced power requirements of sensor nodes. In other words, the available energy that may be harvested from radio frequency signals via a crystal radio receiver, may contain sufficient energy to power milliwatt level instruments and micro-devices. Additionally, the size of a crystal radio antenna may be configured to be relatively small, ranging from a few to tens of centimeters. An antenna of this size may be used with a number of today's wireless sensor node applications.

Harvesting small amounts of energy from radio signals has been studied before, although not in the context of powering nodes in a WSN by AM RF signals. Previous studies have concluded that RF energy is of little utility unless a receiver is very close to a transmitter, such as a cell phone station. An alternate approach would be to introduce an RF signal transmitter for the explicit purpose of transmitting RF energy to a receiver that then harvests the RF energy to perform certain tasks. In other embodiments, such an approach may not be practical in the context of WSNs.

The energy available from RF signals in the unlicensed band, for e.g., the 2.4 GHz spectrum, may be typically too limited to be of any practical use. Such RF power harvesting may be impractical due to (1) very limited power being available (for an antenna size of 100 cm^2, the received power may be less than 0.1 milliwatt), and (2) very limited range (not only may a transmitter be required, but the sensor also may have to be placed very close to the transmitter). On the other hand, the principles on which crystal radios operate may finally permit the successful harvesting of energy from freely available RF signals.

As AM radio signals may be strong enough to power an earplug or a speaker, the energy available from RF signals may be more than past estimates indicated. A typical sensor node may require about 20 milliamps in active mode and 5 microamps in sleep mode, and the operating voltage required may be about 3 volts. Thus, the required power for a typical sensor node is comparable to the power that may be harvested via RF signals. Additionally, low-duty low-energy sensors may not require a transmitter, further reducing the amount of energy needed to power the sensor node. Therefore, RF signals may be a viable "free" and persistent (available 24 hours a day) energy source for a considerable amount of a given radio broadcast receiving area.

II. Estimation of Received Radio Energy

Table 1 below illustrates an estimation of the available RF energy in Princeton, N.J. from AM and FM RF signals transmitted by area radio stations. Through this rough estimation analysis, the "free" RF energy in the Princeton area is shown to be within the 10 milliwatt level. The estimation is based upon the Friis propagation model,

$$P_r = \frac{p_t G_t G_r \lambda^2}{(4\pi)^2 d^2 L},$$

TABLE 1

Radio Stations that can be Received in Princeton, N.J.

Here, p_t, p_r are the power of the transmitter and the receiver, respectively; G_t, G_r are the antenna gains of the transmitter and the receiver, respectively; λ is the wavelength of the RF signal in meters; d is the distance between the transmitter and the receiver; and L is the system losses (L>1). The estimation is based upon various assumptions, such as (1) radio station information (frequency and distance), (2) the transmitting power of AM radio stations being 10 kilowatt and FM stations being 5 kilowatt, (3) the antenna gains, G, are 1 (for a properly designed antenna, G>1), and (4) the system losses, L, are 1.

The results of the estimation indicate that (1) the total power received was 31.120 milliwatts, (2) the AM power received was 31.108 milliwatts, or 99.96% of the total power, and (3) the FM power received was 0.0126 milliwatt, or 0.04% of the total power. The estimation is based on ideal environments. In practice, L is more than 1 and the received power is less than the ideal case. Observing the Friis propagation model reveals that the effect of wavelength on the received power is more than that of the transmission power. Accordingly, signals with longer wavelength, such as AM signals, are much more suitable for RF energy harvesting.

A typical sensor node may require about 41 milliwatts in active mode and 1.5 microwatts in sleep mode. This power requirement is of the same order of magnitude as the power that is available from RF signals. With reasonable conditions, such as the sensor nodes being located near one or more AM radio stations and/or using relatively efficient antennas, the sensor nodes may be powered solely by the AM signal(s) and be kept running uninhibited all of the time. Alternatively, the sensor nodes may be powered primarily by the AM signal(s), if backed up by an on-board energy source.

III. Estimation of Available Energy from Other RF Signal Sources

As noted above, AM signals may include much more energy available for harvesting than FM signals. Energy from other RF signal sources also may be very small when compared with AM signals. For example, the RF signals from cell phones quickly attenuate as a function of distance. As a result, a cell phone signal may be used as a source of energy to power a sensor node only if the distance from the cell phone to the sensor node is about one meter or less.

Energy also may be received from IEEE 802.11.x protocol-based devices and television sets. As IEEE 802.11.x devices operate in the 2.4 GHz band, the energy available for harvesting may be even less than what is available from cell phones. Similarly, due to their high frequency, television signals may contribute very little towards harvestable energy. Therefore, AM signals may provide the best freely available RF source of power for wireless sensor nodes.

IV. Hybrid Scheme

A number of harvesting schemes may be utilized to capture energy from RF signals. As an example, harvesting energy from AM signals may not only be useful for indoor sensor nodes, but could also prove fruitful for outdoor sensor deployments.

In one aspect, the RF harvesting schemes discussed herein may combine two concepts. A sensor node may include crystal radio technology that is operable in conjunction with an energy storage unit, such as a battery and/or a capacitor. Once the output of the crystal radio receiver is connected to act as a source of energy and/or a "charger" to the energy storage unit, the system may be ready for use.

The sensor node may include a RF energy harvesting device that includes a so-called "energy harvesting antenna" operable to capture RF energy. The antenna may harvest AM, as well as FM, or RF signals. The antenna may be a spider antenna, braided antenna, omni-directional antenna, double-braided polyester rope, loop antenna, air coil loop antenna, sparrow antenna, Yagi-Uda antenna, or other type of antenna.

For example, FIG. **8** is an exemplary spider antenna. As shown, the antenna may have a number of legs of differing size. FIG. **9** is another exemplary antenna. Other shapes may be used, such as circular or disk shapes.

The antenna may be a laminated antenna having a number of wires etched onto a semi-conductor or other micro-device. The antenna wires may have either a flat or rounded shape, or be disk shaped. The antenna may have a number of spokes or legs, such as the spider antenna disclosed by U.S. Pat. No. 4,229,742, or the antenna may be a grid antenna similar to the one disclosed by U.S. Pat. No. 7,038,630, both of which are incorporated herein by reference in their entireties. As the antenna characteristics may be determined based upon the bandwidth and gain properties desired for a specific application, alternative antennas may be used.

In one embodiment, for both convenience and cost reduction purposes, a 1950's type of coil or wire antenna connected to the crystal radio receiver may be replaced by modern flexible printed circuit board. Printed circuit board similar to that used in conventional radio frequency identification (RFID) devices may be used. An exemplary RFID antenna is disclosed by U.S. Pat. No. 6,825,754, which is incorporated herein by reference in its entirety. Other types of printed circuit board material and shapes may be used as the antenna.

Once the RF energy is scavenged, the sensor node may regulate the energy within the crystal radio circuit and convert

the RF signals received to a DC signal, such as via a rectifier, without any frequency filtering. As an example, the RF signals harvested may not be filtered via low, high, or band pass filters. After the RF energy harvested passes through the rectifier, the energy may be stored on a super capacitor. However, since the voltage on the two sides of the super capacitor may not satisfy the requirements of the sensor node, a DC/DC converter and/or another capacitor may be employed (such as shown in FIG. **2**, discussed below).

Clean DC power may be available on both sides of the second capacitor. In addition, the DC/DC converter may sample the voltage on the super capacitor, and issue an interrupt to the sensor node once the voltage, which is an indication of the energy being stored and/or harvested, is lower than a certain threshold. The sensor node may then switch to the on-board power source of the harvesting system, such as a battery, a capacitor, or other energy storage device. If the energy being harvested provides a voltage level greater than that of an on-board energy storage device, the energy being harvested may power the sensor node directly, as well as provide a trickle charge to the on-board energy storage device. On the other hand, if the energy being harvested provides a voltage level lower than of the on-board energy storage device, the on-board energy storage device may provide power to the sensor node via a trickle discharge. The harvested RF energy is used to charge the battery under this case.

Therefore, the wireless and self-contained sensor nodes may employ a “hybrid” RF energy harvesting scheme. Each wireless and self-contained sensor node may be equipped with (1) a RE-based energy harvester and (2) an on-board power source. As long as there is enough available power from the RF energy harvester, the sensor node may operate using the RF power. Intermittently, however, the power from the harvester may not be at the threshold required to operate the sensor node. As a result, an interrupt may be generated that switches the sensor node to the on-board power source. The hybrid scheme ensures that the sensor node may be continuously operational while simultaneously greatly lengthening the life-time of the on-board power source.

There are some distinctions between RF energy harvesting as discussed herein and conventional harvesting schemes. With respect to solar cell techniques, the proposed RF harvesting schemes are not affected by the weather or time of day (darkness). The proposed RF harvesting schemes may provide a continuous power supply as most radio stations broadcast around the clock.

Additionally, the proposed RF harvesting schemes may provide more power than solar cells, such as with indoor environments, and at less cost, as typical solar cells may be more expensive than an RF antenna or coil. The costs associated with the proposed schemes may be further reduced if the antenna is implemented using technology similar to that of a RFID tag.

As compared to biomechanics-based harvesting schemes, the proposed RF harvesting schemes may be more suitable for sensor node applications. Conventional biomechanics harvesting methods tend to provide energy on an inconsistent basis and inconveniently toggle sensors periodically to recharge the power source. On the other hand, the proposed RF harvesting schemes may provide a consistent milliwatt-level power source. Toggling may be used with RF harvesting.

With respect to vibration or thermoelectric methods, it may be more difficult to find a vibration or heat source than it is to locate an AM radio station, especially in populated regions of the United States. When a free source is not available, the vibration or thermoelectric based schemes may require an artificial source. In many environments, such as an office or building, installation of such artificial energy sources may not be feasible.

In sum, new RF energy harvesting schemes are described that provide energy to self-contained sensor nodes. The schemes provide an improved crystal radio receiver and harvest AM RF signals as a source of power. The RF harvesting schemes are suitable for indoor applications that involve wireless sensor networks, such as building automation applications.

The RF harvesting schemes may be especially useful in areas having AM stations within about 20 kilometers to satisfy typical sensor node power requirements. However, the effective distance of the harvesting schemes may be extended. The antennas employed may be configured to harvest more energy and provide enhanced gain. Sensor nodes may be configured to be more energy efficient. For example, the sensor nodes may be programmed to operate more efficiently, such as spending more time in various reduced power modes of operation. Additionally, the sensor nodes equipped with RF energy harvesters may be supplemented with other types of energy harvesters, such as solar, piezo-electric, MEMS (micro-electro-mechanical systems), biomechanical, thermoelectric, and other harvesters. The RF harvesting schemes, except for requiring relatively nearby AM radio stations, may have no other substantial apparent limitations, such as the weather, periodic toggling, or other limits.

V. Exemplary RF Energy Harvesting Systems

FIG. **1** illustrates an exemplary passive RF energy harvesting system **100**. The system **100** may include an energy harvesting antenna **102**, a crystal radio receiver **104**, a super capacitor **106**, a DC/DC converter **108**, a sensor node **110**, a local power source **112**, and/or a communication antenna **114**. The system may include additional, fewer, or alternate components.

The crystal radio receiver **104** or crystal set may employ an antenna **102**. The crystal radio receiver **104** may not require a battery or power source except the power received from radio waves via the antenna **102**. The crystal radio receiver **104** may include an antenna wire, a tuning coil of copper wire, a rectifier, and other components. The crystal radio receiver **104** may be a passive radio receiver, not requiring an actively powered amplifier associated with conventional radios. The crystal radio receiver **104** may preserve electrical power from RF signals received via the antenna **102** and convert the RF signals to electronic power. The crystal radio receiver **104** may include various types of antennas and various “low-tech” or traditional electrical circuitry components, such as capacitors, resistors, inductors, and diodes. As such the crystal radio receiver **104** may be simpler and less expensive to manufacture than current “smart” radios, such as cellular phones.

The antenna **102** may be a conventional crystal radio antenna and include copper or silver wire coils, or a ferrite coil. The antenna **102** may be a Yagi, log-periodic, fiberglass, cable, repeater, or other type of antenna, including those discussed elsewhere herein. The antenna **102** may be manufactured from printed circuit board, aluminum, copper, silver, other metals, or other materials. The antenna may omni-directionally collect all of the available AM radio signals currently being received. The shape, size, circumference, and composition of the antenna **102** may be altered for a specific application and/or to enhance the gain associated with the antenna **102**.

The antenna **102** and crystal radio receiver **104** may act independently or in conjunction to harvest RF energy ubiquitously. The crystal radio receiver **104** may require no tuning and resonant with all of the available frequencies. As a result,

energy may be collected simultaneously from a number of radio stations, which may increase the average level of RF energy being harvested. This may be in contrast with typical receivers that may employ RC resonant circuits, which eliminate some RF signals from being harvested. In one embodiment, the antenna may have a physical length of between 10 and 20 cm.

The low power mode may include a number of algorithms and/or software instructions stored in the sensor node that direct the sensor node or an associated processor to conserve or reduce the amount of energy that the sensor node is using. A processing unit on the sensor node may perform reduced or limited processing in low power mode. The radio may change the message routing being employed based upon the amount of RF energy being sensed or harvested. A transmitter may transmit less often in low power mode, or not at all until the level of the RF energy being harvested returns to above a threshold or self-sustaining level. The transmitter may alter the type of signal being transmitted in low power mode. For example, the sensor node may not relay all the received communication packets, and/or the transmitter on the sensor node may transmit at a reduced power level. The transmission at a reduced power level may be intended to only reach the next or closest available sensor node or radio within the network.

The low power mode may include buffering or storing data, instead of constant or even intermittent transmission of information to other sensor nodes. With typical sensor nodes, the operation of the radio and/or transmitting information may require a substantial amount of energy. Therefore, reducing radio transmissions in low power mode may enhance the effectiveness of the RF harvesting schemes discussed herein.

The super capacitor **106** may store the RF energy being harvested. The capacitance of an electrode associated with the super capacitor **106** may be several hundred times the capacitance of a conventional double-layer capacitor. The super capacitor **106** may have one or more electrodes manufactured from titanium, palladium, aluminum, silicon, or other metals. Alternatively, the electrodes may be doped or have titanium, palladium, aluminum, silicon, or other metal coatings. The super capacitor **106** may be similar to those disclosed by U.S. Pat. Nos. 5,585,999 and 5,151,848, which are incorporated herein by reference in their entireties. Alternate types of super or other capacitors may be used.

The DC-to-DC converter **108** may operate to produce an output voltage signal and/or an interrupt signal **116** based upon a signal received from the super capacitor **106** or an electrical parameter of the super capacitor **106** monitored, such as a voltage, current, or other signal. The DC-to-DC converter **108** may be similar to the DC-to-DC converter disclosed by U.S. Pat. No. 6,417,653, which is incorporated herein by reference in its entirety. Alternate DC-to-DC converters may be used.

In one embodiment, the DC-to-DC converter **108** samples the voltage **120** on the super capacitor **106**. The voltage sampled may be a reflection the current level of RF energy being harvested crystal radio receiver **104** and/or stored by the super capacitor **106**. If the voltage sampled falls below a threshold level, such as a level required by the sensor node **110** to operate normally (i.e., with no power operating restrictions), then the DC-to-DC converter may generate a low-power interrupt **116** signal. The sensor node **110** may switch to a low or reduced power operating mode upon the receipt of the low-power interrupt **116**.

The on-board energy storage unit may be a capacitor or battery **112**. The on-board energy storage unit **112** may be on a trickle charge when the voltage sampled **120** from the super capacitor **106** remains above the threshold level (such as the actual battery or capacitor voltage) with the carryover RF energy harvested directly powering the sensor node **110**. Alternatively, the RF energy harvested may be sent directly from the DC-to-DC converter **108** to the sensor node **110** when the level of RF energy being harvested remains at or above the threshold level.

On the other hand, if the low-power interrupt **116** is sent to the sensor node **110**, the sensor node **110** may select **118** or switch to the on-board storage unit **112** as a direct source of power. Alternatively, when the voltage from the DC-to-DC converter falls below the threshold level (such as the actual capacitor or battery voltage), the sensor node **110** may automatically start to be powered by the on-board power storage unit **112** as the storage unit voltage would be higher than the output voltage of the DC-to-DC converter, as can be envisioned by FIG. **1**. Other manners of powering of the sensor node from the super capacitor, either solely or in conjunction with the storage unit, may be used.

The sensor node **110** may be mounted on a device that includes the other components shown in FIG. **1** or be associated with the other components in another fashion. The sensor node **110** may include a communication antenna **114** that provides for wireless communication with other sensor nodes. The sensor node **110** may include the components shown in FIG. **4** and discussed below, in addition to the components illustrated by FIG. **1**. The sensor node may include additional, fewer, or alternate components.

FIG. **1***a* illustrates another exemplary passive RF energy harvesting system **100**. In one embodiment, the system may be targeted to facilitate the powering of sensor nodes in an ad-hoc wireless sensor network. As each sensor node may have communication functionality through an on-board RF module, a message communication subsystem may not be required to be a part of the RF energy harvesting system **100**. Also, the RF energy harvesting system **100** may be purely passive, and thus, no registration with the FCC is required.

As shown in FIG. **1***a*, the system **100** may be connected to the sensor node and its communication antenna. The system **100** may be a band pass and/or all pass filter to match all AM frequencies in order to provide ubiquitous energy harvesting capability and also to harness the maximum available harvestable energy.

As shown in FIG. **1***a*, a super capacitor is introduced as an energy buffer to the rechargeable batteries. Super capacitors have large number of recharge cycles, but limited energy capacity when compared to rechargeable batteries. In one embodiment, since there is bound to be some variation of RF signal strength from time to time and place to place, the harvested RF energy may not be consistent. Thus, as can be seen from FIGS. **1** and **1***a*, harvested energy can be used to power the sensor node or charge the on-hoard power source (such as batteries) on each sensor node. Thus, the demands on recharge cycles of the batteries are relaxed and the battery lifetime may be improved.

FIG. **1***a* also illustrates the interrupt signal. If the harvested RF energy is not enough and falls below a certain threshold, the DC/DC converter (for example, a MAX1674/MAX1675) may trigger the sensor node via an interrupt signal as shown. The processor on the sensor node, upon receiving this interrupt, may measure the voltages of the super capacitor, V1 **122**, and that of the battery, V2 **124**. Depending upon what these measured values are, the sensor node may make intelligent decisions. In one embodiment, the sensor node controls a power switch **126** that is operable to switch between the super capacitor and the batteries as a source of power. An exemplary

flow chart of an interrupt handling process that may be implemented by software on the sensor node is illustrated by FIG. **7**.

FIG. **2** illustrates the circuit exemplary passive RF energy harvesting system **200**. The system **200** may include a crystal radio receiver **202**, an energy harvesting antenna **204**, a DC/DC converter **206**, a voltage output **208**, and an interrupt output **210**. The system may include additional, fewer, or alternate components.

As shown in FIG. **2**, the crystal radio receiver **202** may include a capacitor bank and a rectifier that converts the RF energy being received into a DC signal. The DC signal harvested may be stored upon the super capacitor C**9**. The DC/DC converter **206** may sense the voltage on the super capacitor C**9** and provide an output voltage VCC **210** to the sensor node, as well as the sensor interrupt **210** when the output voltage approximately reaches or falls below a threshold level. The sensor nodes may use RF energy harvesting systems having additional, fewer, or alternate components.

FIG. **2***a* illustrates another embodiment of the circuit of the exemplary passive RF energy harvesting system **200**. With respect to FIG. **1***a*, FIG. **2***a* illustrates in more detail from where V**1 212** and V**2 218** may be sensed. V**1 212** may be sensed from the super capacitor C**2**. V**2 218** may be sensed from the battery. FIG. **2***a* also shows the power switch **214**. The system may include additional, fewer, or alternate components.

VI. Exemplary Network

FIG. **3** illustrates an exemplary network **300** of wireless radios or sensor nodes **312**. The network **300** may utilize a dynamic routing algorithm that permits data transmitted to travel the shortest distance or link **314** between sensor nodes **312** to a destination, which decreases the required transmission time for a given message, as well as the required power level of that transmission. The destination may be another sensor node **312** or a control radio **316**. Each wireless and self-contained sensor node **312** and control radio **316** may have a dedicated processor, a receiver, and a transmitter. The network **300** may include additional, fewer, or alternate components.

Each sensor node **312** may communicate its associated routing information to every nearby or adjacent sensor node **312** or control radio **316**. After a sensor node **312** receives a data transmission, a processor of the sensor node **312** may determine what to do with that data, including whether to retransmit the data to an adjacent or nearby sensor node **312** or control radio **316**. The base station **316** may function as a network controller that directs the overall operation of the network **300**.

The network **300** may provide continuous communication with otherwise unavailable sensor nodes **312**. For instance, some sensor nodes **312** may become obstructed by obstacles, such as equipment, containers, furniture, or other items, or may fail. However, the network **300** may reconfigure itself around blocked paths by redirecting transmissions from one sensor node to the next until communication with a lost sensor node is re-established. The network **300** also may provide enhanced communication reliability between sensor nodes **312** as a single sensor node **312** may be in direct communication with a number of other sensor nodes **312**, as shown in FIG. **3**.

The network **300** may implement IEEE 802.15.4 protocols. Other protocol standards may be used. The network **300** may operate as a mesh network, as described in more detail below. Alternate control or routing algorithms/instructions may be used.

VII. Control of Building Equipment

One application of the sensor nodes described herein relates to a network that controls building equipment. The network may include multiple sensor nodes, each having a wireless radio, as well as one or more control radios or base stations that direct the network. Each sensor node may be a so-called “smart” sensor node that includes a receiver, a transmitter, a processor, memory, one or more sensors, an actuator, and/or other components. Each sensor node may transmit messages to a control radio acting as network controller. Alternatively, the network controller may be a dedicated processor. The network may have one or more network controllers and/or control radios. The term network herein may include the entire network, a sub-set of a network, a number of sensor nodes, one or more network controllers, one or more control radios, or a combination of sensor nodes with one or more network controllers or control radios.

A network controller may assimilate and analyze a number of messages received from a plurality of sensor nodes. In response to each of the messages received, the network controller may determine that a change in the currently operating building equipment, or the operating modes thereof, is in order. Subsequently, the network controller may transmit a message to one or more sensor nodes that direct the operation of building equipment. Upon receiving the message, a sensor node may alter the operation of building equipment.

The sensors associated with the sensor nodes/wireless radios may monitor specific parameters pertaining to building environmental conditions or specific operating equipment. The actuators associated with the sensor nodes may control the operation of certain building equipment. A sensor node may transmit the value of a parameter sensed by a sensor to the network. In response to the values of the parameters received, the network or another sensor node may automatically alter the operation of building equipment, such as by sending messages that operate the actuators that control the building equipment.

For example, the sensors may be temperature sensors that sense the temperature in an area of a building. Each temperature sensor may be connected with a sensor node having a wireless radio, the sensor nodes being dispersed throughout a building. Each sensor node having a temperature sensor may transmit a message to the network regarding the temperature sensed in the building area in which the sensor node is located. In response to the temperature information received, the network may direct that cooling, heating, ventilation, HVAC, emergency, or other building equipment be operated to alter the building environment of the building area in which the sensor node is located.

The network may employ multiple sensor nodes in each building area to monitor temperature. Conventional wall mourned temperature sensors and/or thermostats may be single point sources of information. However, the average value of individual temperature parameters received from a plurality of temperature sensors dispersed in a given building area may better reflect the actual temperature in the building area. Accordingly, the building environmental equipment may be directed to maintain the temperature of a building area closer to the desired temperature based upon the more accurate temperature information received.

The sensors also may be motion sensors that sense motion in a building area. Each motion sensor may be connected with a sensor node having a wireless radio, the sensor nodes being dispersed throughout a building. Each sensor node having a motion sensor may transmit a message to the network regarding the motion sensed in a building area. In response to the motion information received, the network may direct the operation of building equipment.

The motion detected may alert the network that a building area has recently become occupied or unoccupied. In response, the network may ensure that lighting equipment provides adequate light in or near the building area in which motion was sensed. The network may direct that building environmental equipment, such as cooling, heating, ventilation, HVAC, or other equipment, be operated to alter the building environment of the building area. The motion information received also may be used by the network to determine that a security breach has occurred. Accordingly, the network may trigger an alarm, secure passageways, and operate other security equipment in response to the security breach.

A sensor node having a wireless radio may be connected with an identification device located on an individual. After the sensor node located on the identification device transmits a message to the network, the network may determine the identification and/or location of the associated individual. In response, the network may transmit instructions to building environmental equipment to automatically alter the environmental conditions of the specific building area in which the individual is currently located based upon stored or transmitted environmental preferences associated with that individual.

In a building having numerous pieces of operating equipment, it may be desirable to automatically monitor various parameters associated with various pieces of equipment. For instance, in a power plant, refinery, factory, or other plant, it may be advantageous to monitor temperatures, pressures, alarms, tank levels, bilge levels, hydraulic levels, atmospheric conditions, operating pumps or fans, and other parameters. The change in various temperatures, pressures, levels, or equipment operating temperatures may indicate problematic conditions.

The network may automatically identify problematic conditions associated with operating building equipment. The various parameters monitored each may be sensed by a sensor located on a sensor node. The sensor node having a wireless radio may transmit the value of the parameter to the network, either periodically or upon being queried by the network or sensing an out of specification value. The sensor node may determine whether a parameter is within specification, i.e., a predetermined satisfactory range.

If a parameter is not within specification, the network may take corrective action to restore the parameter and/or building conditions to specification. For example, the running speed of a problematic piece of equipment may be shifted, increased, or decreased. The problematic piece of equipment also may be secured and an alternate piece of equipment may be started or placed on line to replace it. Additional, fewer, or alternate courses of action may be taken to correct problematic or out of specification parameters. Sensor nodes may be connected with or part of the equipment being controlled for wireless control of the equipment.

VIII. Mesh Network

In one embodiment, the network may include a number of sensor nodes, each having a wireless radio, arranged as a mesh network that also may be used to locate movable assets and/or operate building environmental equipment. The mesh network provides the capability of routing data and instructions between and among the network of radios. The mesh network permits data to be efficiently transmitted from one radio in the network to the next until the data reaches a desired destination.

The mesh network may be implemented over a wireless network or partially wireless network. Each sensor node having a radio within the network may function as a repeater that transmits data received from adjacent sensor nodes having radios to other nearby sensor nodes that are within range. The coverage area of the mesh network may be increased by adding additional radios. As a result, a network may be established that may cover an area of desired size, such as a floor of a building or an entire building.

Each sensor node having a radio within the mesh network is typically only required to transmit data as far as the next sensor node having a radio within the network. Hence, if a sensor node having a wireless radio has a limited power supply, the reduction in the distance that each sensor node is required to transmit permits lower power level transmissions, which may extend the operating life of the on-board power supply.

A number of protocols may be used to implement the mesh network. The sensor nodes may implement a protocol that uses low data rates and low power consumption. As noted above, the mesh network may employ devices that use very small amounts of power to facilitate significantly increased battery or power supply life. In some situations, power supply life may be extended by minimizing the time that the radio device of the sensor node is "awake" or in normal power using mode, as well as reducing the power at which a signal is transmitted.

Alternatively, the sensor nodes having wireless radios may implement a protocol that uses moderate or high data rates and power consumption. For instance, the sensor nodes may implement IEEE 802.11 protocols. An IEEE 802.11 LAN may be based on a cellular architecture where the system is subdivided into cells, where each cell is controlled by a base station. Other protocols may be implemented.

Additionally, by reducing the distance between sensor nodes, each sensor node having a wireless radio may be able to transmit signals at a reduced power level, which may extend the life of a power supply while the signals transmitted remain strong enough to reach an adjacent sensor node having a radio. The sensor nodes within the network may be synchronized such that each sensor node talks or listens at a particular time. Alternatively, one or more control radios may be generally active, while the remaining radios remain predominantly passive. The control radios may be hardwired directly to a power supply such that they are not confined by a limited power supply.

The mesh network may utilize the Zigbee protocol or other IEEE 802.15.4 Low-Rate Wireless Personal Area Network (WPAN) standards for wireless personal area networking. Zigbee is a published specification set of high level communication protocols designed for use with small, low power digital radios based upon the IEEE 802.15.4 standard. Other IEEE 802.15 standards also may be implemented, including those using Bluetooth or other WPAN or WLAN protocols or any other protocol.

The mesh network of sensor nodes may employ a dynamic routing algorithm. As a result, the mesh network may be self configuring and self mending. Each sensor node within the network may be able to identify neighboring sensor nodes. After receiving a message, a receiving sensor node may determine that it is not the sensor node closest to the destination and/or that it should not relay the message to another sensor node based upon the currently known configuration of operating sensor nodes. The receiving sensor node may wait a predetermined period and listen for another sensor node with a radio to relay the message. If after a predetermined time, the sensor node determines that the message has not been relayed as expected, the receiving sensor node may transmit or relay the message to a nearby sensor node.

By transmitting messages to only reach nearby or adjacent sensor nodes in the network, the messages within the network

may be transmitted at lower power. The low power transmission requires less energy from the on-board power supply of each sensor node. Additionally, the low power transmissions by the sensor nodes prevent one message from occupying the entire network and permits messages to be simultaneously transmitted from different sensor nodes and travel throughout the network of sensor nodes in parallel.

IX. Exemplary Sensor Nodes

FIG. **4** illustrates an exemplary sensor node or wireless radio **410**. The sensor node **410** includes a processor **412**, a wireless radio frequency transmitter and/or receiver **414**, a sensor **416**, an actuator **418**, a memory **420**, a clock **422**, a speaker **424**, a microphone **426**, and an on-board power supply **428**. The sensor node **410** may include additional, different, or fewer components.

For example, the sensor node **410** may be free of the sensor **416**, actuator **418**, memory **420**, clock **422**, speaker **424**, the microphone **426**, and/or power supply **428**. The sensor node **410** may include the processor **412** and the wireless transmitter and/or receiver **414**. For instance, the sensor node **410** may comprise the processor **412**, the wireless radio frequency transmitter and/or receiver **414**, the sensor **416**, the actuator **418**, and the power supply **428**. Or the sensor node **410** may comprise the processor **412**, the wireless radio frequency transmitter and/or receiver **414**, the sensor **416**, and the power supply **428**. The sensor node **410** may include other combinations employing additional, different, or fewer components.

In one embodiment, the sensor node **410** may be operable to automatically control building equipment and locate movable items within a building. In another embodiment, the sensor node **410** may be portable, such as in the case of being mounted upon a movable item, or affixed at a specific location or to an immovable item. The sensor node **410** may be a controller, actuator, sensor, locator or other device in a security, fire, environment control, HVAC, lighting, or other building automation system. The sensor node **410** may determine its present location, sense conditions within a building, report conditions within a building, generate a signal representative of a building condition, and/or respond to an interrogator. The sensor node **410** also or alternatively may actuate building control components. As a controller, the sensor node **410** may be free of the sensor **416** and/or the actuator **418**. In another embodiment, the sensor node **410** is a wireless device free of wired connections to other devices making the sensor node **410** self-contained and/or portable.

The sensor **416** may be a single sensor or include multiple sensors. The sensor **416** may be a temperature, pressure, humidity, fire, smoke, occupancy, air quality, flow, velocity, vibration, rotation, enthalpy, power, voltage, current, light, gas, CO_2, CO, N_2, O_2, chemical, radiation, fluid level, tank level, motion, Global Positioning System (GPS), infrared, or other sensor or combination thereof. The sensor **416** also may be a limit or proximity switch. Alternate sensors may be used.

The sensor **416** may be a motion sensor that detects when a portable sensor node **410** is moving. If it is sensed that the sensor node **410** is moving, the processor **412** may wake the sensor node **410** up from a sleep mode that draws less energy from the power supply **428**. Upon waking up, the sensor node **410** may transmit via the wireless transmitter **414** to the network a message indicating that sensor node **410** is moving.

The sensor **416** may be motion sensor that detects when there is movement within a predetermined distance. For example, the sensor **416** may be wall mounted to detect when an individual has entered a specific building area. If the building area was previously unoccupied, the sensor node **410** on which the sensor **416** is mounted may transmit a message to the network that the building area is no longer unoccupied. As a result, the network may direct that the environmental conditions be altered accordingly, such as increase the temperature during cold weather, decrease the temperature during hot weather, turn on one or additional lights, or adjust the room to the individual's personal preferences.

The sensor **416** may be a GPS unit capable of receiving GPS signals and determining the location of the sensor node **410**. The GPS unit may be able to determine the latitudinal and longitudinal coordinates, as well as the elevation, of the sensor node **410**. The location of the sensor node **410** determined by the GPS unit may be subsequently transmitted to the network via the wireless transmitter **414**.

The actuator **418** may be a single actuator or include multiple actuators. The actuator **418** may be a valve, relay, solenoid, speaker, bell, switch, motor, motor starter, turbine generator, motor generator, diesel generator, pneumatic device, damper, or pump actuating device or combinations thereof. For example, the actuator **412** may be a valve for controlling flow of fluid, gas, or steam in a pipe, or a damper controlling or redirecting air within an air duct. As another example, the actuator **412** may be a relay or other electrical control for opening and closing doors, releasing locks, actuating lights, or starting, stopping, and shifting motors and pumps. As a further example, the actuator **412** may be a solenoid that opens or closes valves, dampers, or doors, such as for altering the flow of fluid or air within piping or ducting. Alternate actuating devices also may be used.

The sensor node **410** may function as a controller or base station. The controller may be positioned at either a known or an unknown location. As a controller, the sensor node **410** interacts with other sensor nodes **410** for control or reporting functions.

The processor **412** is capable of processing data and/or controlling operation of the sensor node **410**. The processor **412** may be a general processor, digital signal processor, application-specific integrated circuit (ASIC), field programmable gate array, analog circuit, digital circuit, network of processors, programmable logic controller, or other processing device. The processor **412** may have an internal memory.

The sensor node **410** also may have a memory unit **420** external to the processor **412**. The memory unit **420** may store data and instructions for the operation and control of the sensor node **410**, such as discussed herein. Additional or alternate types of data also may be stored in the memory unit **420**.

A program may reside on the internal memory or the memory unit **420** and include one or more sequences of executable code or coded instructions that are executed by the processor **412**. The instructions may include monitoring a signal associated with radio frequency energy being harvested via a crystal radio receiver, the radio frequency energy being used to at least partially power a sensor node. The instructions also may include automatically reducing the amount of power being expended by the sensor node if the magnitude of the signal monitored approximately reaches or falls below a threshold level. The instructions may include directions to accomplish other functionality described herein.

The program may be loaded into the internal memory or memory unit **420** from a storage device. The processor **412** may execute one or more sequences of instructions of the program to process data. Data may be input to the data processor **412** with a data input device and/or received from a network. The program and other data may be stored on or read from machine-readable medium, including secondary storage devices such as hard disks, floppy disks, CD-ROMS, and

DVDs, or other forms of machine readable medium, either currently known or later developed.

The processor **412** is capable of directing the transmission or reception of data by the wireless transmitter or receiver **414**, the speaker **424** or the microphone **426**. For example, the processor **412** may direct the acoustic speaker **424** to transmit an ultrasound signal. The processor **412** may also direct the microphone **426** to receive an ultrasound signal and determine a distance from another device as a function of the received signal. Alternatively or additionally, the processor **412** may direct the wireless transmitter or receiver **414** to transmit data for determining the distance. Additionally or alternatively, the wireless transmitter **414** transmits a determined distance or distances as well as data regarding the processes and operation of the sensor **416** and/or the actuator **418**.

The wireless transmitter and receiver **414** or the speaker **424** may be alternate wireless transmitters capable of transmitting a signal for distance determination. Similarly, the wireless receiver **414** and microphone **426** may be alternative wireless receivers capable of transmitting a signal for distance determination.

FIG. **5** illustrates a floor layout for a network of sensor nodes having wireless radios **510** operating with one or more control radios **522** within a building **524**. The sensor nodes **510** may be dispersed throughout the building **524**. One or more of the sensor nodes **510** may be located in each room or other building area. Alternate dispersed arrangements of the sensor nodes **510** may be provided. While one control radio **522** is shown, a plurality of control radios **522** may be provided in other embodiments. Additional, different or fewer sensor nodes **510** and control radios **522** may be provided. While shown as a single floor of a building **524**, the network of sensor nodes **510** and control radios **522** may be distributed over multiple floors, a portion of the floor, a single room, a house, a structure, or any other building **524** or portion thereof.

The various sensor nodes **510** may be of the same configuration or a different configuration than each other. For example, some of the sensor nodes **510** may correspond to sensor arrangements, while other sensor nodes **510** may correspond to actuator arrangements. The same or different communication device, such as a wireless radio frequency transmitter and/or receiver, may be provided for each of the sensor nodes **510**. Alternatively, different communications mechanisms and/or protocols are provided for different groups of the sensor nodes **510**. The sensor nodes **510** may operate in an integrated manner for implementing one or multiple types of building automation control. Alternatively, different networks may be provided for different types of building automation, such as security, HVAC, heating, ventilation, and fire systems.

The sensor nodes powered by RF energy as discussed herein may be useful for a wide variety of applications, in addition to the building control functionality described above. For instance, the applications may include environmental and human body monitoring to military surveillance, building automation, and industrial monitoring. Each sensor node may facilitate one or more control, homeland security, reconnaissance, or other tasks. In one embodiment, the sensor node may be implanted internally within a patient, and sense and transmit data pertaining to a biological characteristic of the patient. The sensor nodes may be used for other applications.

X. Exemplary Method

FIG. **6** illustrates an exemplary RF energy harvesting method. The method may include harvesting RF energy **602**, storing the RF energy harvested **604**, monitoring a signal associated with the RF energy harvested **606**, and selecting an operating mode based upon the level of the signal monitored **608**. The method may include additional, fewer, or alternate actions.

The method may include harvesting RF energy **602**. RF energy may be harvested via a crystal radio receiver as discussed herein. Most of the energy harvested may be scavenged from AM radio signals. The RF energy may be harvested ubiquitously. The RF energy may be used to primarily or solely power a self-contained sensor node.

The method may include storing the RF energy harvested **604**. The RF energy or an associated signal may be measured from a super capacitor or other energy storage means. In one aspect, the RF energy harvestor may be used in unison with another type of energy harvester, such as a solar, biomechanical, thermoelectric, or vibration driven device.

The method may include monitoring a signal associated with the RF energy **606**. A voltage on the super capacitor may be monitored. Other signals related to the RF energy harvested also may be monitored.

The method may include selecting an operating mode based upon the level of the signal monitored **608**. The operating mode selected may relate to power constraints imposed upon the sensor node. If the level of the signal being monitored, such as a voltage signal or other signal, falls below a threshold level, the sensor node may be directed to operate in a low power mode, as discussed herein, to conserve energy until the amount of RF energy being harvested returns to a self-sustaining level with respect to the operating power requirements of the sensor node.

XI. Exemplary Method

FIG. **7** illustrates an exemplary interrupt handling method **700**. The method **700** may be implemented by software on the sensor node. As shown, the method **700** may use a state variable K having 2 states. When K=1, the power switch in FIG. **2***a* may connect pin A to pin Out, which in turn is connected to the pin labeled VCC. The voltage of pin VCC, which is connected to the sensor node, is equal to the output voltage of the DC/DC converter. Thus, in this case, the sensor node is powered through the energy harvester via the super capacitor and DC/DC converter. On the other hand, when K=2, the power switch connects pin B to pin Out and in this case, the sensor node is powered by the battery.

Ts in FIG. **7** is the wake-up period (which is configurable through software depending upon the application). The sensor node wakes up repetitively with time period of Ts. Each time when the sensor node wakes up, it may sense the environment, process the data, and transmit the date to the sink, if necessary. Then the sensor node may enter sleep mode, which costs almost no energy.

Tm in FIG. **7** is the maximum wake-up period allowed by the system. If Ts>Tm, the wake-up period is longer than the upper limit required by the system. Thus, the sensor node cannot provide spontaneous samples to satisfy the quality of service (QoS) requirements of the network.

Tp in FIG. **7** denotes a continuous block of time during which harvested energy is enough to support the continuous operation of the sensor node to execute for a time Te, which is the minimum time required by a sensor node to complete sensing tasks as required by an application. In other words, each time the sensor node wakes up, it may have to execute for at least a period of Te. And the sensor node may have to make a decision as to whether it powers itself from the energy harvester or through the battery for this amount of time. The

following brief analysis is presented to describe the novel sensor node operation that may be facilitated through the energy harvesting circuit.

Let the capacity of the super capacitor be represented by C. Then, the instantaneous energy E stored in the super capacitor is given by:

$$E=½CV_1^2.$$

If power rating of the sensor node is P, then the following equation holds

$$E+D'T_p=PT_e,$$

where E' is the derivative of E with respect to time Thus,

$$\begin{aligned} T_p &= \frac{PT_e - E}{E'} \\ &= \frac{PT_e - \frac{1}{2}CV_1^2}{CV_1V_1'}, \end{aligned}$$

where V_1' is the derivative of V**1** and V_1' can be estimated in practice by taking the difference of the V**1** values at consecutive time intervals.

The flow chart shown in FIG. **7** may be described as follows. After receiving the interrupt **702**, the sensor node sends a control signal to the power switch such that the sensor node is powered through the battery **704**, since the energy on the capacitor may be depleted soon. The voltages V**1** and V**2** are measured by the sensor node **706**. Tp is also computed based on V**1** **708**, as shown in the above equation.

V**2** is checked to see if it is low **710**. If it is, then all of the energy is going to be depleted soon. Recall that when the interrupt occurred, V**1** is already low. Thus, in this case, neither the energy harvester nor the battery can power the sensor node. The sensor node must take emergency actions, such as backup data **712** and notify its neighbors **714**. Finally, the sensor node sets Ts to be equal to Tp **716**, as well as sets K to 1 **718**. The rationale being that since the energy in the battery is going to be depleted soon, the node should wait in sleep mode **732** until enough energy has been harvested by the RF energy harvester.

When V**2** is not low, the decision is based on V**1**. If V**1** is low such that Tm≤Tp **720**, which means that the energy harvester cannot satisfy the sensor node energy requirements, then the sensor node once again has no choice but to use power from the battery source. Since there is enough battery energy (recall that V**2** is not low), the sensor node can be powered by the battery **728** through the current wake-up period Ts **726**. The neighbors also may be notified **730**. However, note that the energy from the harvester can still be used to charge the battery through the DC/DC converter. Thus, the system still benefits from the energy harvester even though the node is not powered directly by the energy harvester.

If V**1** is high enough to support the minimal energy requirements of the sensor during its wake-up period, i.e., Tm>Tp, then the sensor node can increase its wake-up period. In this case, Ts is set to be Tp **722** and the sensor node is powered by the energy harvester through the DC/DC converter **724**.

To summarize, the embodiments discussed herein facilitate the following complex sensor node behaviors: (1) switching the operating mode on the sensor node, such as standby or sleep modes; (2) sending a notification message to a sink via other sensor nodes; (3) saving important data to the flash memory on the sensor node, in case it is lost; (4) changing a sampling rate and transmission rate, and reducing the rates according to the voltages V**1** and V**2**, (5) adjusting an energy weighting factor in the network routing metric (if the voltages of the sensor node are not high enough, the use of this node as a router to route other wireless message packets is minimized or avoided), and (6) switching the input power source from the RF energy harvester to a battery.

The methods and systems discussed herein may use one, two, or more antennas. If two antennas are used, one antenna may be dedicated to the sensor node or communications unit, and the other antenna may be dedicated to the RF energy harvesting system, such as shown in the Figures. As both the sensor node and the energy harvester each may have their own dedicated antenna, switching a single antenna between the sensor node and the energy harvester may be alleviated.

The operational mode of the harvesting system and/or the sensor node may be switched by the sensor node itself. Additionally or alternatively, the RF energy harvester discussed herein may trigger the sensor node and provide voltage measurements. For energy conservation purposes, the harvesting system discussed herein may not switch operation modes based on. RF signals.

Therefore, the RF energy harvesters described herein may be directly connected to sensor nodes, purely passive and not needing to pass FCC requirements, and/or based on a bandpass or all pass filter for ubiquitous and wide spectrum RF energy harvesting. The systems discussed herein may facilitate advanced sensor behaviors. The system modes (active, standby and sleep) may be triggered by an interrupt signal and controlled by the sensor node, as compared to altering the operating mode according to received RF signals. The designs of the energy harvesting antenna may be different from known antennas. A super capacitor and/or a DC/DC converter may be employed by the energy harvester. Based on efficiency, size, and costs, the DC/DC converter may provide benefits as compared to transformers. A buffered energy storage system may be constructed by the super capacitor and one or more rechargeable batteries. The harvesting system may improve battery life time.

While the invention has been described above by reference to various embodiments, it should be understood that many changes and modifications can be made without departing from the scope of the invention. The description and illustrations are by way of example only. Many more embodiments and implementations are possible within the scope of this invention and will be apparent to those of ordinary skill in the art. The various embodiments are not limited to the described environments, and have a wide variety of applications including integrated building control systems, environmental control, security detection, communications, industrial control, power distribution, and hazard reporting.

It is intended in the appended claims to cover all such changes and modifications which fall within the true spirit and scope of the invention. Therefore, the invention is not limited to the specific details, representative embodiments, and illustrated examples in this description. Accordingly, the invention is not to be restricted except in light as necessitated by the accompanying claims and their equivalents.

We claim:

1. A method of passive radio frequency energy harvesting, the method comprising:

harvesting radio frequency energy using a crystal receiver;

powering a processing unit only from the radio frequency energy being harvested when the radio frequency energy being harvested, or an indication of the amount of radio frequency energy being harvested, is above a threshold level;

generating an interrupt signal to switch the processing unit to a low power mode when the radio frequency energy

being harvested, or the indication of the amount of radio frequency energy being harvested, falls below the threshold level; and

alternatively powering the processing unit only from an on-board power source when the radio frequency energy being harvested, or the indication of the amount of radio frequency energy being harvested, is below the threshold level.

2. The method of claim **1**, wherein the crystal receiver employs an antenna that is fabricated from printed circuit board.

3. The method of claim **1**, wherein the radio frequency energy harvested is increased by a super capacitor before being used to power the processing unit.

4. The method of claim **1**, wherein the on-board power source is a battery or a capacitor.

5. The method of claim **1**, wherein the crystal receiver employs a ferrite coil antenna.

6. The method of claim **1**, wherein the radio frequency energy is harvested ubiquitously.

7. A method of passive radio frequency energy harvesting, the method comprising:

harvesting radio frequency energy using a crystal receiver;

powering a processing unit only from the radio frequency energy being harvested when the radio frequency energy being harvested, or an indication of the amount of radio frequency energy being harvested, is above a threshold level, wherein the processor unit is a self-contained sensor node operable to direct the operation of building equipment to control an environment of a building;

generating an interrupt signal to switch the processing unit to a low power mode when the radio frequency energy being harvested, or the indication of the amount of radio frequency energy being harvested, falls below the threshold level; and

alternatively powering the processing unit only from an on-board power source when the radio frequency energy being harvested, or the indication of the amount of radio frequency energy being harvested, is below the threshold level.

8. The method of claim **7**, wherein the processor unit has power requirements of greater than 10 milliwatts.

(57) **ABSTRACT**

An R.F. energy collection circuit, provides a low-loss R.F. front end tuned to minimize lost power in R.F. bands commonly used for communications for passing substantially coherent R.F. signals received therefrom, a rectifier circuit coupled to receive coherent R.F. energy from the front end, and an energy storage circuit coupled to receive energy from the rectifier circuit.

R.F. ENERGY COLLECTION CIRCUIT FOR WIRELESS DEVICES

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority from U.S. Provisional Patent Application Ser. No. 61/187,687, filed Jun. 17, 2009, entitled EXTENDED RANGE PASSIVE RFID SYSTEM and incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

The present invention relates generally to the application of ideal materials sets and frequency-selective antennas to collect R.F. energy and to greatly extend the range of passive radio-frequency identification (RFID) systems.

BACKGROUND OF THE INVENTION

U.S. Pat. No. 6,027,826 to de Rochemont, et al. discloses articles and methods to form oxide ceramic on metal substrates to form laminate, filament and wire metal-ceramic composite structures using liquid aerosol spray techniques. U.S. Pat. Nos. 6,323,549 and 6,742,249 to de Rochemont, et al. disclose articles that comprise, and methods to construct, an interconnect structure that electrically contacts a semiconductor chip to a larger system using at least one discrete wire that is embedded in amorphous silica ceramic, as well as methods to embed passive components within said interconnect structure. U.S. Pat. Nos. 5,707,715 and 6,143,432 to de Rochemont, et al. (the '715 and '432 patents) disclose articles and methods to relieve thermally-induced mechanical stress in metal-ceramic circuit boards and metal-ceramic and ceramic-ceramic composite structures. U.S. Pat. No. 6,027,826 to de Rochemont, et al. disclose articles and methods to form oxide ceramic on metal substrates to form laminate, filament and wire metal-ceramic composite structures using liquid aerosol spray techniques. U.S. Pat. Nos. 6,323,549 and 6,742,249 to de Rochemont, et al. disclose articles that comprise, and methods to construct, an interconnect structure that electrically connects a semiconductor chip to a larger system using at least one discrete wire that is embedded in silica ceramic, as well as methods to embed passive components within said interconnect structure. U.S. patent application Ser. No. 11/479,159 (U.S. Pub. No. 2007/0003781) (hereinafter "de Rochemont '159") discloses articles and methods that laminate passive components (resistors, capacitors, inductors) on an exposed or a buried microelectronic surface using liquid aerosol sprays or inkjet deposition systems. U.S. patent application Ser. No. 11/660,042 (Pub. No. 2007/0139976) (hereinafter "de Rochemont '042) discloses articles and methods that laminate passive components on an exposed surface layer or a buried microelectronic layer to form a power management device using laminated resistors, capacitors, inductors or transformers. U.S. Pat. No. 7,405,698 is used to miniaturize artificial magnetic conducting ground planes and form meta-material dielectrics that, in combination with de Rochemont '159, enable electrically small antennas. The contents of each of these references are incorporated herein by reference as if laid out in their entirety.

RFID systems allow an object to be remotely identified by a radio frequency "interrogator" signal, which activates a "chirp" or "read" signal from the RFID tag. Passive RFID systems do not have any internal power sources (such as battery elements) within the tag to avoid maintenance needs and, consequently, will have read ranges—(the distance from which the tag can be remotely identified)—limited to 65 to 100 feet. This is the case because the interrogator signal must activate and power the "read signal" from the RFID transponder. Therefore, the interrogator signal must be powerful to simultaneously overcome signal path losses between the read head and the RFID tag, to activate the "read" signal, and still be detectable by the remote read head. State-of-the-art passive RFID systems that incorporate surface-acoustic wave systems will require power levels of −15 dB to −18 dB simply to activate the chirped read signal.

RFID systems are used to manage assets in inventory and during transport. Recently, piracy and theft during logistical transport has developed a need for passive RFID sensors that can not only report asset location, but additional information that might indicate whether or not the asset has been compromised or tampered to a surveillance vehicle located several miles away from the asset, such as an unmanned aerial vehicle.

Therefore, methods that enable passive RFID sensors to remotely report the location or tampering of an asset at distances up to and exceeding a distance of 10 miles is desirable. It is also desirable that such an RFID system have a planar structure so that it may be concealed in the wall of a container to protect it from being detected, damaged or destroyed prior to or during the time an asset is tampered.

SUMMARY OF THE INVENTION

One embodiment of the present invention provides an R.F. energy collection circuit, comprising a low-loss R.F. front end tuned to minimize lost power in R.F. bands commonly used for communications for passing substantially coherent R.F. signals received therefrom, a rectifier circuit coupled to receive coherent R.F. energy from the front end, and an energy storage circuit coupled to receive energy from the rectifier circuit.

The storage circuit may include a tank circuit. The storage circuit may include a rechargeable battery. The rectifier circuit may include a center-tapped transformer.

The R.F. front end may include a folded dipole antenna formed in composite material having an effect permittivity which varies $\leq 5\times10^{-2\circ}\,\mathrm{C.}^{-1}$. The effective permittivity of the composite material may be made to vary $\leq 9\times10^{-3\circ}\,\mathrm{C.}^{-1}$.

The circuit may further comprise an RFID circuit coupled to receive response transmission energy from the energy storage circuit. The RFID circuit may include an interrogation reception circuit and an ID transmission circuit, and further wherein the interrogation reception circuit is coupled to connect energy from the energy storage circuit to power the ID transmission circuit in response to an interrogation signal being received by the interrogation reception circuit.

The circuit may further comprise a wireless appliance coupled to receive power from the energy storage circuit.

The present invention describes methods and embodiments that extend the read range of easily concealable passive RFID sensor systems by minimizing activation energies and harvesting power from the RF environment.

An RFID circuit generally includes a stray RF energy collection circuit, an storage device for the collected stray RF energy, an ID transmission circuit and an interrogation reception circuit adapted for coupling stored energy to the ID transmission circuit in response to an interrogation signal sent to the RFID circuit. The energy collection circuit may have resonant antenna sections tuned to frequencies used for global communications and navigation. Narrow conductance band frequency-selective antenna tuning may be used for the interrogator-receive and tag transmit circuits, and also for the read-head antenna system that interrogates the RFID circuit. Meta-material dielectrics may be used to apply the aforementioned antenna turnings to electrically small antennas embedded within the meta-material dielectric. The ID transmit circuitry may optionally include an oscillator, a power amplifier, and modulation circuitry that encodes specific information about the status of an asset associated with the RFID circuit for transmission back to the remote read head.

BRIEF DESCRIPTION OF THE DRAWINGS

For a better understanding of the present invention, together with other and further aspects thereof, reference is made to the following description taken in conjunction with the accompanying figures of the drawing, wherein:

FIG. **1** is a schematic representation of an extended range passive RFID architecture that harvests energy from the RF environment to power the signal sent to the remote interrogator;

FIG. **2** depicts the return loss of a broadband antenna element that is tuned to selectively absorb energy from signals commonly found in the modern RF environment;

FIG. **3** depicts the return loss of narrow conductance band antenna that eliminates the need for additional RF filtering stages in the RFID tag or the read head;

FIG. **4** depicts a physical design of a planar RFID device; and

FIG. **5**. shows TABLE 1, which compares the power losses in a conventional RF front-end used in code-division multiple access (CDMA) to the power losses in an RF front-end that contains a narrow conductance band antenna.

DETAILED DESCRIPTION OF THE INVENTION

The read range of an RFID device, passive or otherwise, is determined by the residual power detectable in dBWatts (dBW) at the remote read head, P_r, which is determined by:

$$P_r = P_t - L_p + G_t + G_r - L_t - L_r, \tag{1}$$

where P_t is the radio frequency (RF) power transmitted by the RFID tag, L_p is the signal path loss, G_t and G_r are the antenna gain of the RFID tag (t) and the remote read head (r) respectively, L_t and L_r represent the transmission line losses between the transmitter circuit and the tag antenna and the read antenna and the read head receiver circuitry, with all values reported in dBW except for the antenna gains which are reported in dBi. The free space signal path loss is determined by:

$$L_p = 36.6 + 20\log(f[\text{MHz}]) + 20\log(d[\text{miles}]), \tag{2}$$

where f is the signal frequency in megahertz units (MHz) and d is the distance in units of miles. Therefore, at a distance of 10 miles the free space path loss for a 900 MHz signal is significant (~116 dBW). Signal loss due to scattering and attenuation caused by features in the landscape and buildings can easily drive path loss values up to 140-160 dBW, which makes the task of remotely detecting the RFID tag quite challenging.

In order to extend the range of remote RFID devices it therefore is essential to increase the transmitted power at the RIFD tag (P_t), increase the gain of the tag and read head antennas (G_t) and (G_r), respectively, and minimize the transmission line losses in the interconnects placing the transmission circuitry in electrical communication with the tag antenna (L_t), and the receiver circuitry in electrical communication with the receive antenna (L_r). As described in the background, the present invention provides a means to minimize transmission line losses (L_t and L_r) by embedding low resistivity alloys or noble metals (copper, silver or gold) in amorphous silica glass ceramic, which is used in optical fiber applications for its ultra-low dielectric loss ($\tan \delta \approx 2\times10^{-5}$).

A limitation to state-of-the-art passive RFID tags is that the interrogator signal is used to activate and power the chirp signal. At a distance of 10 miles, the power of a 900 MHz interrogator signal is already reduced by −116 dBW (in free space). If it requires −15 dBW to −18 dBW to activate the transmitted read signal, the total loss (assuming no transmission line losses i.e., L_t and L_r=0) for the round trip is −247 dBW to −250 dBW. This level of loss makes it extremely difficult to operate a passive RFID system, particularly if the interrogator signal powers the chirp signal. This limitation is overcome by the current invention.

Reference is now made to FIGS. **1** & **2** which depict features of the present invention. The extended range passive RFID **101**, shown in FIG. **1**, uses a selective-frequency broadband antenna system **103** to harvest ambient power from the RF environment. The antenna system is a dipole antenna folded in such a way that current vectors along the dipole arms form capacitive loads (when aligned in anti-parallel directions) and inductive loads (when aligned in parallel directions). By properly folding the arms one can construct one or more RF filtering stages by inserting capacitive and inductive load elements in series or in parallel to create frequency selective pass bands. Further details of this method and technology are described in U.S. Provisional Patent Application Ser. No. 61/355, 755, filed Jun. 17, 2010 and entitled FREQUENCY SELECTIVE DIPOLE ANTENNAS, the contents of which are hereby incorporated by reference herein.

FIG. **2** shows the selective frequency response of a folded dipole that is designed to be resonant at the primary frequencies for civilian communications and navigation, with resonant frequencies at the 450 MHz cellular band **151**, the 900 MHz bands used for the American Mobile Phone System (AMPS) bands **153**, the 1600 MHz global positioning satellite (GPS) bands **155**, the 1800 MHz and 1900 MHz global system mobile (GSM) bands **157**, and the 2.5 GHz (2500 MHz) WiFi bands **159**. This selective-frequency broadband antenna system **103** allows the passive RFID system **101** to harvest energy from the RF environment that is readily available from the civilian wireless communications infrastructure. The selective-frequency broadband antenna need not be tuned to these frequencies, and can be tuned to an arbitrary set of frequencies that could readily harvest power from any given RF environment. These bands are cited here because they are widely used in the global civilian communications infrastructure and can readily supply RF power to the passive tag in most locations around the world.

The RF power harvested by selective-frequency broadband antenna element **103** is then fed through a rectification circuit **105**, which may either be a diode bridge or a center-feed transformer **107** as shown in FIG. **1**, which stores the energy in a lumped circuit (LC) storage tank **109**. The LC storage tank **109** may comprise one or more inductor coils, capacitor and/or resistor elements, or may comprise any device that is capable of storing the harvested RF power for later use. This energy harvested from the RF environment is now available to augment the power of the transmitted signal P_t from the passive RFID tag, which is needed to extend its read range.

Alternatively to the RF ID circuit shown in fig one, the energy collection and storage circuitry described thus far in components **103**, **105**, **107** and **109** may be used for providing power to any sort of wireless device or appliance. This includes, but is not limited to cell phones, computing devices, GPS devices, pagers, radios, etc. For this purpose, it may be desirable to include a rechargeable battery **108** and diode **110**, connected in phantom, to store power either from storage tank **109** or directly from rectifier **105**.

As referenced above and in the background, conventional passive RFID systems rely on the interrogator signal to both activate and supply the power for the transmitted chirp signal. At long distances, such as 10 miles or more, the interrogator power is already diminished by signal path losses, so a −15 dBW to −18 dBW loss associated with activating the chirp signal is highly undesirable. It is therefore a desirable embodiment of the present invention to utilize a weak interrogator signal to activate a switch **111** that dumps the harvested and stored RF power into the transmit circuitry of the extended range passive RFID system **101**. Reference is now made to FIGS. **1**, **3**A, **3**B and Table 1 of FIG. **5** to illustrate preferred embodiments of the invention to maximize performance in this regard. The tag's interrogator-receive antenna **113** registers the interrogator signal, which it then passes through a rectifier circuit **115**. Rectifier circuit **115** is representational in FIG. **1** and may be a center-feed transformer or a rectifying diode bridge. The interrogator-receive circuitry may additionally contain command circuitry (not shown) that may receive digitally encoded instructions to alter the modulation encoding (also not shown) in the RFID system's **101** transmit circuitry **117** to communicate information about the asset, such as maximum exposed temperatures, applied g-forces, or evidence of tampering. The weak interrogator is then used as a base current for a power transistor that functions as the switch **111**. The LC storage tank **109** supplies both the collector voltage V_c and the collector I_c for the switch **111**, while the rectified weak interrogator signal provides base current for the switch **111**. Since gain for the switch **111** is a function of the base current derived from the weak interrogator signal, it may be desirable for the interrogator-receive circuit to also contain a power management or collection system **119** that allows the base current supplied to the switch **111** to obtain a threshold value that maximizes the transmitted power P_t from the extended range passive RFID system. The emitter current and voltage emerging from the switch **111** is then used to power the transmit circuitry **117** that may optionally include an oscillator, a power amplifier, and modulation circuitry that encodes specific information about the asset's status for transmission back to the remote read head.

As alternatively referred to above, the representational transmit circuitry **117** may also be embodied by any form of wireless device or appliance such as cell phones, computing devices, GPS devices, pagers, radios, etc. while components **103**, **105**, **107** and **109** work as a recharging and power supply.

As noted above, it is desirable to minimize transmission line losses in the tag and the read head. This may also include RF front-end losses from filters that are used to improve overall signal integrity in the system. To this end, it is a preferred embodiment of this invention to utilize antenna elements that have been tuned to have narrow conductance band frequency selectivity as shown in FIGS. **3**A, **3**B using the current vector alignment methods described above. In this instance, the RF filtering stages built in to the folded dipole antenna limit the resonant band of the interrogator-receive antenna **113** and the transmit antenna **121** to a narrow communications band **201** of signal frequencies. Since this antenna tuning provides a voltage standing wave ratios (VSWR) frequency **203** bandwidth that is much wider than the conductance bandwidth **201**, this antenna tuning both filters spurious noise from the interrogator-receive antenna **113** and eliminates undesirable emissions from the transmit antenna **121**.

Table 1 provides an analysis of the power that is wasted in an RF front-end designed for code division multiple access (CDMA) communications using conventional filters to an RF front-end that uses a narrow conductance band antenna. Not only is there a 60% reduction in the power wasted through the front-end circuit, the resultant power savings additionally allow a power amplifier (PA) contained in the transmit circuitry **117** to operated at lower back-off voltage, which allows it to operate at much higher efficiency. It is therefore a preferred embodiment of the present invention to use narrow conductance band frequency-selective antenna tuning not just for the interrogator-receive and tag transmit circuits, but also for the read-head antenna system.

Signal path loss can be reduced by using a lower signaling frequency. For instance, 10-30 MHz signaling frequencies reduce the free space path loss from the tag to the receive head from −116 dBW to 74-80 dBW. Lower signaling frequencies consequently require antennas that are much larger in size to achieve higher efficiencies and high gain. This proportionally makes the device much larger in overall size. For the purpose of concealment, it is therefore advantageous to have a smaller device that operates at lower frequency and also has high gain and excellent power efficiency characteristics. It is therefore a preferred embodiment of the invention to use meta-material dielectrics that apply the aforementioned antenna turnings to electrically small antennas embedded within the meta-material dielectric.

Finally, it is desirable that the present invention be easily concealable within a planar surface of the asset or its container. Reference is now made to FIG. **4** to describe a preferred embodiment of the invention in which the antenna systems **251** are configured on a thermally stable miniaturized artificial magnetic conducting (AMC) ground plane **253** that comprises high-energy ceramic meta-material dielectric. To improve system planarity it is also desirable to have all the additional circuit elements, such as the power transistors, diodes, passive components (transformers, inductors, capacitors, resistors)—(not shown in FIG. **4**)—laminated on the backside **255** of said AMC ground plane **253** adjacent to any active semiconductor chip components that may be needed to complete the circuit.

All of the electronic components shown and represented in FIG. **1** may be optimally constructed using the techniques described in the patents and patent applications incorporated herein by reference.

Although the invention has been described with respect to various embodiments, it should be realized this invention is also capable of a wide variety of further and other embodiments within the spirit and scope of the present invention.

What is claimed is:

1. An extended range passive RFID transponder with an R.F. energy collection circuit, comprising:

a first narrow conductance band antenna forming an interrogator receive antenna and in electrical communication with the gate electrode of a transistor switch,

wherein the first narrow conductance band antenna comprises a folded dipole that is resonant at a frequency or frequencies that match the frequency or frequencies of an interrogator signal for the RFID transponder, providing −30 dB or better signal isolation from RF frequencies that do not match the frequency or frequencies of the interrogator signal,

an ID transmission circuit;

an R.F. energy collection circuit, comprising:

a low-loss R.F. front end including a folded dipole antenna tuned to minimize lost power in two or more R.F. bands commonly used for communications for passing substantially coherent R.F. signals received therefrom;

wherein the low-loss R.F. front end comprises low-resistivity alloys or noble metals embedded in a composite material having an effective permittivity that varies $5\times10^{-2\circ}$ C.$^{-1}$;

a rectifier circuit coupled to receive coherent R.F. energy from the front end; and

an energy storage circuit coupled to receive energy from the rectifier circuit and coupled to provide energy to the ID transmission circuit in response to an interrogation signal received by the first narrow conductance band antenna.

2. The transponder of claim **1**, wherein the storage circuit includes a tank circuit.

3. The transponder of claim **1**, wherein the storage circuit includes a rechargeable battery.

4. The transponder of claim **1**, wherein rectifier circuit includes a center-tapped transformer.

5. The transponder of claim **1**, wherein the effective permittivity of the composite material varies $<9\times10^{-3\circ}$ C.$^{-1}$.

6. The transponder of claim **1**, wherein the ID transmission circuit is coupled to the R.F. energy collection circuit through the transistor having the gate electrode coupled to the first narrow conductance hand antenna.

7. The transponder of claim **6**, further comprising a resonant tank circuit connected between the first narrow conductance band antenna and the transistor gate electrode.

8. The transponder of claim **1**, further comprising a wireless appliance coupled to receive power from the energy storage circuit.

9. The transponder of claim **1**, wherein the folded dipole antenna is resonant in two or more separate R.F. bands.

10. The transponder of claim **1**, wherein the energy storage circuit and the passive RFID system is functional without a battery.

(57) **ABSTRACT**

A charge apparatus including a natural energy conversion module, an energy converter, an energy transmitter, an energy receiver, and an electricity storage device is provided. The natural energy conversion module receives the natural energy and converts the natural energy into a first electric energy. The energy converter is electrically connected to the natural energy conversion module and converts the first electric energy into a wireless energy. The energy transmitter is electrically connected to the energy converter and transmits the wireless energy. The energy receiver receives the wireless energy and converts the wireless energy into a second electric energy to charge an external apparatus. The energy transmitter monitors the current charge status of the external apparatus so as to adjust transmitting the wireless energy. The electricity storage device is electrically connected to the natural energy conversion module to store the first electric energy.

CHARGE APPARATUS

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation-in-part of prior U.S. patent application Ser. No. 12/833,218 filed on Jul. 9, 2010. The entirety of the above-mentioned patent application is hereby incorporated by reference herein and made a part of specification.

TECHNICAL FIELD

The disclosure relates to a charge apparatus, and more particularly, to an energy-converting charge apparatus.

BACKGROUND

Natural energy resources offer low pollution, high regeneration, and easy collection. Wind and solar energy are two ideal natural energy resources compared to coal, petroleum, and gas for thermal energy generation (which have limited quantities and are highly pollutive) and water for hydraulic energy generation (which is restricted by the terrain). Particularly, a stable and continuous energy supply can be ensured if different natural energy resources are combined.

In recent years, application of solar energy in energy generation has been increasing significantly. Solar panels are broadly deployed by various manufacturers to reduce the cost in power consumption and set up an environment-friendly manufacturing site. How to effectively convert a natural energy into electricity and store it has become one of the major subjects in today's energy and resources research. A light emitting device which uses solar energy as its power supply is disclosed in U.S. Pat. No. 6,994,448.

However, electric energy is the essential element for driving electronic devices and appliances. Conventionally, electric energy is generated by using thermal energy, hydraulic energy, or nuclear energy and then conducted to electronic devices and appliances to charge the same through transformers, power cables, and receptacles. Since the conventional technique for driving electronic devices and appliances depends on the contact between different elements, the charging effect may not be satisfactory due to oxidized contact points and sparks, electric shocks, power failures may be caused. In addition, different electronic devices and appliances require different power cables and charge apparatuses. Thus, the cables may be tangled together if different electronic products are used, and the working area of these electronic products may be limited by the position of the power source and the lengths of the cables.

Some wireless charging techniques have been developed in recent years. For example, an optical charge apparatus including a light source and a sensor connected to the light source is disclosed in U.S. Patent Publication 2007/0114967. When the sensor detects that a portable electronic apparatus having photovoltaic cells as its receiving device is getting close to the light source, the sensor controls the light source to emit light. The light emitted by the light source reaches the photovoltaic cells in the portable electronic apparatus to charge the portable electronic apparatus. However, because the photovoltaic cells are used as the receiving end of the energy transmission, this charge apparatus disclosed in the U.S. Patent Publication 2007/0114967 has a low photoelectric conversion rate therefore is not so practical.

A non-radiative energy wireless transmission technique is disclosed in PCT Publication WO 2007/008646 A2, wherein the energy is transmitted through resonance coupling between two resonance structure apparatuses.

Additionally, a wireless energy transmission system is disclosed in U.S. Patent Publication 2006/0266917, wherein an energy signal is issued and the position of an electronic product to be charged is determined at the receiving end through a reflection mechanism so as to charge the electronic product. A wireless charging system adaptable to a vehicle is disclosed in U.S. Pat. No. 5,982,139. When the wireless charging system receives a positioning signal of the vehicle, the wireless charging system charges the vehicle. The receiving end of the wireless charging system includes a logic circuit for detecting whether the electric volume of the vehicle reaches a charging standard. The wireless charging system can charge only one vehicle at one time.

In U.S. Patent Publication 2007/00019693, the position of an electronic product that is to be charged is determined through an image captured by a camera, and the electric volume of the electronic product is detected to determine whether to turn on a wireless energy transmission function. Furthermore, an optical receiver is disclosed in U.S. Pat. No. 6,972,904, wherein a diffractive optical element (DOE) is adopted for diffracting a light beam to a reflection plane, and the reflection plane is suitable for focusing the light beam into a specific direction.

SUMMARY

A charge apparatus is provided herein.

According to one of the exemplary embodiments of the charge apparatus, the charge apparatus includes a natural energy conversion module, an energy converter, an energy transmitter, an energy receiver, and an electricity storage device. The natural energy conversion module receives the natural energy and converts the natural energy into a first electric energy. The energy converter is electrically connected to the natural energy conversion module and converts the first electric energy into a wireless energy. The energy transmitter is electrically connected to the energy converter and transmits the wireless energy. The energy receiver receives the wireless energy and converts the wireless energy into a second electric energy to charge an external apparatus. The energy transmitter monitors the current charge status of the external apparatus so as to adjust transmitting the wireless energy. The electricity storage device is electrically connected to the natural energy conversion module to store the first electric energy.

According to one of the exemplary embodiments of the charge apparatus, the charge apparatus includes a natural energy conversion module, an energy converter, a transmitting antenna, a receiving antenna, and an electricity storage device. The natural energy conversion module receives the natural energy and converts the natural energy into a first electric energy. The energy converter is electrically connected to the natural energy conversion module and converts the first electric energy into an electromagnetic wave. The transmitting antenna is electrically connected to the energy converter and transmits the electromagnetic wave in a wireless manner. The receiving antenna receives the electromagnetic wave in a wireless manner and converts the electromagnetic wave into a second electric energy to charge an external apparatus. The transmitting antenna monitors the current charge status of the external apparatus so as to adjust transmitting the electromagnetic wave. The electricity storage device is connected to the receiving antenna to store the second electric energy.

According to one of the exemplary embodiments of the charge apparatus driven by a natural energy, the charge apparatus includes an energy receiver and an external apparatus. The energy receiver receives a wireless energy and converts the wireless energy into a second electric energy. The external apparatus is charged by the energy receiver wherein a charge status of the external apparatus is monitored so as to adjust the wireless energy transmitting.

Several exemplary embodiments accompanied with figures are described in detail below to further describe the disclosure in details.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings are included to provide further understanding, and are incorporated in and constitute a part of this specification. The drawings illustrate exemplary embodiments and, together with the description, serve to explain the principles of the disclosure.

FIG. **1** is a block diagram illustrating a charge apparatus driven by a natural energy according to a first exemplary embodiment of the present disclosure.

FIG. **2** is a block diagram illustrating a solar electricity generating apparatus applied to the charge apparatus in the first exemplary embodiment.

FIG. **3** is a block diagram illustrating a wind electricity generating apparatus applied to the charge apparatus in the first exemplary embodiment.

FIG. **4** is a block diagram illustrating a charge apparatus driven by a natural energy according to a second exemplary embodiment of the present disclosure.

FIG. **5** is a block diagram illustrating a charge apparatus driven by a natural energy according to a third exemplary embodiment of the present disclosure.

FIG. **6** is a block diagram illustrating a charge apparatus driven by a natural energy according to a fourth exemplary embodiment of the present disclosure.

FIG. **7** is a block diagram illustrating an electromagnetic wave charge apparatus according to a fifth exemplary embodiment of the present disclosure.

FIG. **8**A is a diagram illustrating a charge apparatus driven by a natural energy according to a sixth exemplary embodiment of the present disclosure.

FIG. **8**B is an enlarged view of area A in FIG. **8**A.

FIG. **9** is a diagram illustrating how an energy transmitter monitors the charge status of an external apparatus.

FIG. **10** is a diagram illustrating how an energy transmitter determines whether there is any obstacle in a transmission path.

FIG. **11** is a diagram illustrating a charge apparatus driven by a natural energy according to a seventh exemplary embodiment of the present disclosure.

FIG. **12** is a diagram illustrating a charge apparatus driven by a natural energy according to another exemplary embodiment of the present disclosure.

FIG. **13** is a diagram illustrating how an energy transmitter transmits a wireless energy to an energy receiver according to another exemplary embodiment of the present disclosure.

FIG. **14** is a diagram illustrating how an energy transmitter transmits a wireless energy to an energy receiver according to another exemplary embodiment of the present disclosure.

FIG. **15** is a block diagram illustrating a charge apparatus driven by a natural energy according to another exemplary embodiment of the present disclosure.

DETAILED DESCRIPTION OF DISCLOSED EMBODIMENTS

FIG. **1** is a block diagram illustrating a charge apparatus driven by a natural energy according to a first exemplary embodiment of the present disclosure.

Referring to FIG. **1**, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **100**, an energy transmitter **102**, and an energy receiver **104**. The natural energy conversion module **100** receives a natural energy and converts it into a first electric energy. The energy transmitter **102** receives the first electric energy and converts it into an energy. The energy transmitter **102** may be a light emitting device or a radio wave transmitter. For example, the light emitting device may be a light emitting diode (LED), an incandescent, a laser diode, or other collimated light sources, and the radio wave transmitter may be a transmitting antenna that can convert the first electric energy into an electromagnetic wave and radiate it into the space. In addition, a sensor (not shown) may be disposed on the energy transmitter **102** for detecting the position of the energy receiver **104**. When it is detected that the energy receiver **104** is getting close, the sensor drives the energy transmitter **102** to start working. The energy receiver **104** receives the energy and converts it into a second electric energy to be consumed by an external apparatus **106**. The energy receiver **104** may be a photo detector or a radio wave receiver. For example, the photo detector may be a photovoltaic semiconductor, a photodiode, a phototransistor, or a photovoltaic cell. If the energy receiver **104** is a radio wave receiver, the energy receiver **104** is composed of a receiving antenna that receives the electromagnetic wave and converts it into the second electric energy. In addition, the natural-energy-driven charge apparatus may further include an electricity storage device (not shown) for storing the second electric energy. The energy transmitter **102** and the energy receiver **104** may be induction coils. Energy is transmitted between the energy transmitter **102** and the energy receiver **104** (as indicated by the dotted arrow in FIG. **1**) without any conventional power cable. For example, if the energy transmitter **102** is a light emitting device, the light it generates can be transmitted to the energy receiver **104** through an optical fiber, and if the energy transmitter **102** is a radio wave transmitter, the electromagnetic wave it generates can be transmitted to the energy receiver **104** through waveguide (when the electromagnetic wave is a radio wave) or the air.

Referring to FIG. **1** again, the natural energy conversion module **100** may be a solar electricity generating apparatus or a wind electricity generating apparatus. When the natural energy conversion module **100** is a solar electricity generating apparatus, it converts solar energy into the first electric energy. For example, as shown in FIG. **2**, the solar electricity generating apparatus includes a photovoltaic cell array **200**, a charge battery array **202**, a unidirectional current device **204**, and an outer lead **206**. The photovoltaic cell array **200** includes a plurality of solar chips **210** for receiving solar energy and converting it into the first electric energy. The charge battery array **202** includes a plurality of charge batteries **212** for storing the first electric energy. The unidirectional current device **204** is located between the photovoltaic cell array **200** and the charge battery array **202**. The unidirectional current device **204** may be a blocking diode, and this blocking diode can prevent power consumption caused by countercurrent. The outer lead **206** connects the photovoltaic cell array **200**, the unidirectional current device **204**, and the charge battery array **202**. On the other hand, when the natural energy conversion module **100** is a wind electricity generating apparatus, it converts wind energy into the first electric energy. For example, as shown in FIG. **3**, the wind electricity generating apparatus includes a wind driven generator **300**, a digital inverter **302**, and an electricity storage device **304**. The wind driven generator **300** converts wind energy into the first electric energy. The digital inverter **302** converts the voltage of the first electric energy. The electricity storage device **304** stores the first electric energy.

FIG. **4** is a block diagram illustrating a charge apparatus driven by a natural energy according to a second exemplary embodiment of the present disclosure.

Referring to FIG. **4**, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **400**, an electromagnetic wave transmitter **402**, and an electromagnetic wave receiver **404**. The natural energy conversion module **400** receives a natural energy and converts it into a first electric energy. The electromagnetic wave transmitter **402** receives the first electric energy and converts it into an electromagnetic wave (for example, a laser wave or a radio wave). The electromagnetic wave transmitter **402** may be a laser diode (LD) or any other device that can emit a directional light energy. After the electromagnetic wave transmitter **402** generates the laser wave, the light energy is transmitted to the electromagnetic wave receiver **404** through optical fiber or through peer-to-peer transmission with the air as the transmission medium. In addition, a sensor (not shown) may be disposed on the electromagnetic wave transmitter **402** for detecting the position of the electromagnetic wave receiver **404**. When it is detected that the electromagnetic wave receiver **404** is getting close, the sensor drives the electromagnetic wave transmitter **402** to emit the electromagnetic wave. The laser wave may be implemented by using a GaAs visible or invisible laser (for example, a laser having its wavelength between 600 nm and 1600 nm), or a GaN visible or deep ultraviolet laser (for example, a laser having its wavelength between 200 nm and 600 nm). Besides, the laser wave may also be an InP laser (for example, a laser having its wavelength between 1100 nm and 1800 nm). The laser wave may further be a solid-state laser, a gas laser, or a LD.

Referring to FIG. **4** again, the electromagnetic wave receiver **404** in the natural-energy-driven charge apparatus receives the aforementioned laser wave and converts it into a second electric energy to be consumed by an external apparatus **406**. For example, the electromagnetic wave receiver **404** in the present embodiment includes a photo detector. The photo detector may be a photovoltaic semiconductor, a photodiode, a phototransistor, or a photovoltaic cell. The photo detector is applicable to the detection of both visible and invisible lights. The electric energy converted by the photo detector is usually a current source. The current source can be converted into a voltage source. Alternatively, the second electric energy is first stored in an electricity storage device (for example, a battery) **408** and then used for driving the backend external apparatus **406**, e.g. a light emitting device, a mobile device, or a display device, etc. For example, a GaAs laser with wavelength 980 nm emits a 100 mW laser beam and transmits the laser beam to the photo detector through optical fiber to generate a current of 40 mA. Herein this current of 40 mA is enough for driving a small bulb. In the second embodiment, the transmission medium between the electromagnetic wave transmitter **402** and the electromagnetic wave receiver **404** may be air or optical fiber. The natural energy conversion module **400** can be referred to the natural energy conversion module **100** in the first embodiment.

FIG. **5** is a block diagram illustrating a charge apparatus driven by a natural energy according to a third exemplary embodiment of the present disclosure.

Referring to FIG. **5**, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **500**, a radio wave transmitter **502**, and a radio wave receiver **504**. The natural energy conversion module **500** receives a natural energy and converts it into a first electric energy. The natural energy conversion module **500** can be referred to the natural energy conversion module **100** in the first embodiment. The radio wave transmitter **502** is connected to the natural energy conversion module **500**, receives the first electric energy and converts the first electric energy into a radio wave. In addition, a sensor (not shown) may be disposed on the radio wave transmitter **502** for detecting the position of the radio wave receiver **504**. When it is detected that the radio wave receiver **504** is getting close, the sensor drives the radio wave transmitter **502** to emit the radio wave. The radio wave receiver **504** is disposed opposite to the radio wave transmitter **502**, receives the radio wave and converts the radio wave into a second electric energy to be consumed by an external apparatus **506**. The radio wave transmitter **502** includes a transmitting antenna **508**, and the transmitting antenna **508** converts the first electric energy into an electromagnetic wave and radiates it into the space. The radio wave receiver **504** also includes a receiving antenna **510** for receiving the radio wave and converting it into the second electric energy. The natural-energy-driven charge apparatus may further include an electricity storage device **512**. The electricity storage device **512** is connected to the radio wave receiver **504** and stores the second electric energy to be consumed by the external apparatus **506**. In the present embodiment, the radio wave transmitter **502** and the radio wave receiver **504** may be induction coils, and the transmission medium between the radio wave transmitter **502** and the radio wave receiver **504** may be waveguide or air.

FIG. **6** is a block diagram illustrating a charge apparatus driven by a natural energy according to a fourth exemplary embodiment of the present disclosure.

Referring to FIG. **6**, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **600**, a light emitting device **602**, and a photo detector **604**. The natural energy conversion module **600** receives a natural energy and converts it into a first electric energy. The natural energy conversion module **600** can be referred to the natural energy conversion module **100** in the first embodiment. The light emitting device **602** is connected to the natural energy conversion module **600**, and which receives the first electric energy and converts it into a light source, wherein the light source may be an electromagnetic light (for example, a :laser wave) or a non-electromagnetic light (for example, the light emitted by a LED or a fluorescent bulb). In the present embodiment, the light emitting device **602** may be a LED or a fluorescent bulb. In addition, a sensor (not shown) may be disposed on the light emitting device **602** for detecting the position of the photo detector **604**. When it is detected that the photo detector **604** is getting close, the sensor drives the light emitting device **602** to emit light. Because the photo detector **604** in the present embodiment can detect light of related wavelength, a high photoelectric conversion rate over 60% is achieved. Thus, the energy conversion rate is increased considerably compared to that in a photovoltaic cell. Besides, the wavelengths of light absorbed by a photovoltaic cell range from 0.4 μm to 1.1 μm. In the present disclosure, the selection of wavelength range is made more flexible by adopting a photo detector corresponding to a light source.

Referring to FIG. **6** again, the photo detector **604** is disposed opposite to the light emitting device **602**, receives the aforementioned light source and converts the light source into a second electric energy to be consumed by an external apparatus **606**. The photo detector **604** may be a photovoltaic semiconductor, a photodiode, a phototransistor, or a photovoltaic cell, wherein the phototransistor is usually composed of a photodiode and a transimpedance amplifier. The transimpedance amplifier converts the current supplied by the photodiode into a voltage so that a voltage source is output. Besides, in the present embodiment, the natural-energy-driven charge apparatus further includes a first electricity storage device **608**. The first electricity storage device **608** is connected to the photo detector **604** for storing the second electric energy.

FIG. **7** is a block diagram illustrating an electromagnetic wave charge apparatus according to a fifth exemplary embodiment of the present disclosure.

Referring to FIG. **7**, the electromagnetic wave charge apparatus in the present embodiment includes an energy transmitter **700** and an energy receiver **702**. The energy transmitter **700** receives a first electric energy and converts it into an electromagnetic wave (for example, a radio wave or a laser wave). The energy receiver **702** receives the electromagnetic wave from the energy transmitter **700** through a transmission medium **704** and converts the electromagnetic wave into a second electric energy. In addition, a sensor (not shown) may be disposed on the energy transmitter **700** for detecting the position of the energy receiver **702**. When it is detected that the energy receiver **702** is getting close, the sensor drives the energy transmitter **700** to start working. The transmission medium **704** may be air, optical fiber, or waveguide, wherein the optical fiber may be quartz optical fiber or plastic optical fiber. Moreover, the electromagnetic wave charge apparatus in the present embodiment further includes an energy supply module **706** for supplying the first electric energy to the energy transmitter **700**. The energy supply module **706** may be a general power supply or a natural energy conversion module. For example, the general power supply may be a battery or mains electricity, and the natural energy may be solar energy or wind energy. Finally, the second electric energy converted by the energy receiver **702** is supplied to and consumed by an external apparatus **708**.

FIG. **8**A is a diagram illustrating a charge apparatus driven by a natural energy according to a sixth exemplary embodiment of the present disclosure.

Referring to FIG. **8**A, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **800**, an energy converter **802**, an energy transmitter **803**, and a plurality of energy receivers **804***a* and **804***b* (only two of which are illustrated in FIG. **8** as examples).

The natural energy conversion module **800** receives a natural energy **N1** (for example, a solar energy) and converts it into a first electric energy EP**1**. In the present embodiment, the natural energy conversion module **800** includes conversion units **800***a*, **800***b*, and **800***c*. The conversion units **800***a*, **800***b*, and **800***c* may be photovoltaic cells, and these photovoltaic cells are electrically connected with each other and converts the solar energy into the first electric energy EP**1**. In another embodiment, the natural energy **N1** includes at least one of solar energy, water energy, geothermal energy, wave energy, tidal energy, wind energy, and biomass energy.

Referring to FIG. **8**A again, the energy converter **802** converts the first electric energy EP**1** into a wireless energy W. The wireless energy W may be a magnetic energy or an electromagnetic wave, wherein the electromagnetic wave may be a microwave, a light wave, a radio wave, or a laser wave.

The energy transmitter **803** is electrically connected to the energy converter **802**. The energy transmitter **803** receives the wireless energy W and transmits it in a wireless manner. To be specific, when the energy converter **802** converts the first electric energy EP**1** into the wireless energy W which can be conveniently transmitted in a wireless manner, an energy splitting device (not shown) in the energy transmitter **803** splits the wireless energy W into a plurality of energy portions and transmits these energy portions to the energy receivers **804***a* and **804***b* of a plurality of external apparatuses in a wireless manner. The energy splitting device may be disposed on the energy transmitter **803** to simplify the apparatus.

Then, the energy receivers **804***a* and **804***b* receive the wireless energy W in a wireless manner and convert the received wireless energy W into a second electric energy EP**2** to be consumed by external apparatuses **806***a* and **806***b*. Herein the external apparatuses **806***a* and **806***b* may be cell phones or notebook computers. In addition, the wireless energy W in the present embodiment may be laser. Since laser is highly collimated, easy to integrate, and free of radio frequency (RF) interference, the highly intensive wireless energy W to the energy receivers **804***a* and **804***b* can be exactly transmitted.

As shown in FIG. **8**A, the energy receivers **804***a* and **804***b* may be connected to the external apparatuses **806***a* and **806***b* by, for example, the circuits **808***a* and **808***b*, and the circuits **808***a* and **808***b* transmit the converted second electric energy EP**2** to the external apparatuses **806***a* and **806***b* to charge the external apparatuses **806***a* and **806***b*.

Additionally, the energy transmitter **803** in the present embodiment may also transmit a microwave signal MW to locate the energy receiver **804***a* or **804***b*. In other words, in the present embodiment, the position of the external apparatus **806***a* or **806***b* is determined by using microwave. Compared to the conventional positioning technique in which a regular light beam is used, positioning within a large area can be carried out by using microwave due to the high directivity of microwave. Besides, because the transmission of microwave is not affected by the weather (unlike a regular light beam), after the energy transmitter **803** determines the position of the energy receiver **804***a* or **804***b*, it can transmit energy to the external apparatus **806***a* or **806***b* in the specific direction so that the energy transmission efficiency can be improved.

Referring to FIG. **8**A again, the natural-energy-driven charge apparatus in the present embodiment further includes an electricity storage device **805**. The electricity storage device **805** is electrically connected to the natural energy conversion module **800**, and the first electric energy EP**1** is stored in the electricity storage device **805** through circuit transmission. After that, the energy converter **802** converts the first electric energy EP**1** into the wireless energy W, and the energy transmitter **803** transmits the wireless energy W to the energy receivers **804***a* and **804***b* in a wireless manner.

To be specific, in the present embodiment, a converter (not shown) may be disposed on the energy receivers **804***a* and **804***b* to convert the wireless energy W into the second electric energy EP**2**, so that the second electric energy EP**2** can be consumed by the external apparatuses **806***a* and **806***b*. In another embodiment, the energy transmitted between the energy receivers **804***a* and **804***b* and the external apparatuses **806***a* and **806***b* may be through waveguide instead of the circuits **808***a* and **808***b*.

For example, in another embodiment, the energy transmitter **803** may be a transmitting antenna, such as a dipole antenna, a panel antenna, a microstrip antenna, a multiple element dipole antenna, a Yagi antenna, a parabolic dish, an omniantenna, a grid antenna, or a disc antenna. The energy receivers **804***a* and **804***b* may be an receiving antenna, such as a dipole antenna, a panel antenna, a microstrip antenna, a multiple element dipole antenna, a Yagi antenna, a parabolic dish, an omniantenna, a grid antenna, or a disc antenna.

The transmitting frequency of the wireless energy W maybe within the range of 110~150 kHz. The transmitting frequency of the wireless energy W maybe within the range of 350~375 kHz. The transmitting frequency of the wireless energy W maybe within the range of 10~15 MHz. The transmitting frequency of the wireless energy W maybe within the range of 470~860 MHz. The transmitting frequency of the wireless energy W maybe within the range of 850~950 MHz. The transmitting frequency of the wireless energy W maybe 2.45 GHz.

A dipole antenna would include two identical conductive elements such as metal wires or rods, which are usually bilaterally symmetrical Several different variations of the dipole are also used, such as the folded dipole, short dipole, cage dipole, bow-tie, and batwing antenna. Dipoles may be used as standalone antennas themselves, but they are also employed as feed antennas (driven elements) in many more complex antenna types, such as the Yagi antenna, parabolic antenna, reflective array, turnstile antenna, log periodic antenna, and phased array. Yagi antenna is consisting of a driven element and additional parasitic elements. The parasitic element is slightly longer (typically 5% longer) than the driven dipole. a parabolic dish antenna would include a metal parabolic reflector with a small feed antenna suspended in front of the reflector at its focus, pointed back toward the reflector. The reflector is a metallic surface formed into a paraboloid of revolution and usually truncated in a circular rim that forms the diameter of the antenna. Parabolic antennas is nonresonant, so it can function over a wide range of frequencies, that is a wide bandwidth. To change the frequency of operation would involve replacing the feed antenna with one that works at the new frequency. Some parabolic antennas receive at multiple frequencies by having several feed antennas mounted at the focal point, close together.

FIG. **8**B is an enlarged view of area A in FIG. **8**A. As shown in FIG. **8**B, the energy transmitter **803** includes a transmitting end TE**1** and a receiving end TE**2**. The transmitting end TE**1** transmits the wireless energy W to the energy receiver **804***a* in a wireless manner. The receiving end TE**2** receives an instruction signal S1 from the energy receiver **804***a*, wherein the instruction signal S1 provides an energy transmission information to the energy transmitter **803**. In the present embodiment, the energy transmission information may be a current charge status of the external apparatus **806***a*.

On the other hand, the energy receiver **804***a* in the present embodiment may further include a receiving end TE**3** and a transmitting end TE**4**. The receiving end TE**3** receives the wireless energy W from the energy receiver **803**, and the transmitting end TE**4** transmits the instruction signal S1 to the energy receiver **803**. To be specific, when the receiving end TE**3** of the energy receiver **804***a* receives the wireless energy W from the transmitting end TE**1** of the energy transmitter **803**, the transmitting end TE**4** of the energy receiver **804***a* transmits the instruction signal S**1** to the receiving end TE**2** of the energy receiver **803**, wherein the instruction signal S**1** represents the energy transmission information (i.e., the current charge status of the external apparatus **806***a*).

FIG. **9** is a diagram illustrating how the energy transmitter **803** monitors the charge status of the external apparatus **806***a*.

Referring to FIG. **9**, when the external apparatus **806***a* is not fully charged yet (for example, $t=t_1$ and $t=t_2$), the energy transmitter **803** continues to supply the wireless energy W. Contrarily, after the external apparatus **806***a* is fully charged (for example, $t=t_3$), the intensity E**2** corresponding to the instruction signal S changes and is transmitted back to the energy transmitter **803** so that the energy transmitter **803** stops supplying the wireless energy W. As described above, the energy transmitter **803** can monitor the charge status of the external apparatus **806***a* according to the instruction signal S**1**, so as to determine whether to continues supplying the wireless energy W. Thereby, the power consumption can be reduced.

Additionally, as shown in FIG. **8**B, in the present embodiment, the energy receiver **804***a* may further include a controller **807**. The controller **807** executes a logic operation. The energy receiver **804***a* transmits a displacement signal S2 to the energy transmitter **803** according to the operation result of the controller **807** such that the energy transmitter **803** can adjust the position or the angle of the transmitting end TE1.

To be specific, when the energy receiver **804***a* starts to transmit the wireless energy W, the controller **807** performs the position adjustment to find the maximum value of the wireless energy W within the area in which the energy receiver **804***a* is located. Meanwhile, the energy receiver **804***a* keeps receiving the wireless energy W. When the intensity E**1** of the received wireless energy W is lower than a predetermined threshold, the transmitting end TE**4** of the energy receiver **804***a* outputs the displacement signal S**2** to notify the energy transmitter **803** to adjust the position or the angle of the transmitting end TE**1**. Namely, the energy transmitter **803** adjusts its transmitting position or the transmitting angle when the received energy (for example, an electromagnetic wave energy or a magnetic energy) of the energy receiver **804***a* is lower than a predetermined threshold. So that an optimal working point can be maintained between the transmitting end TE1 of the energy transmitter **803** and the receiving end TE3 of the energy receiver **804***a*.

It should be noted that in the present embodiment, even though the wireless energy W is transmitted in a single direction, other signals may be transmitted in a single direction or in two different directions. As described above, the energy transmitter **803** transmits the microwave signal MW to locate the energy receiver **804***a* or **804***b*. After that, the energy receiver **804***a* transmits the displacement signal S**2**, and the energy transmitter **803** determines whether to adjust the position or direction of the transmitting end TE**1** according to the displacement signal S**2**. Namely, the signal transmission between the transmitting end TE**4** and the receiving end TE**2** is not limited to the single direction from the transmitting end TE**4** to the receiving end TE**2**. Instead, it could be bidirectional.

Moreover, as shown in FIG. **10**, besides monitoring the charge status, the transmitting end TE**4** and the receiving end TE**2** may also simultaneously provide an information indicating whether an obstacle O blocking the energy transmission exists in the transmission path. Namely, the energy transmission information may be a transmission path information. Referring to FIG. **10**, when the obstacle O does not exist in the transmission path between the receiving end TE3 and the transmitting end TE**1** (for example, t<t1), the instruction signal S instructs the energy transmitter **803** to supply the wireless energy W continuously. Contrarily, when the obstacle O exists in the transmission path (for example, t**1**<t<t**2**), the energy E**2** of the instruction signal S changes to notify the energy transmitter **803** to stop supplying the wireless energy W. After the obstacle O leaves the transmission path (for example, t>t2), the intensity E2 of the instruction signal S changes again to notify the energy transmitter **803** to supply the wireless energy W again.

As described above, through the obstacle monitoring function, energy loss caused by invalid transmission is prevented, and meanwhile, any damage caused by the transmitted wireless energy to a living creature that passes through the transmission path is also prevented. In other words, the charge apparatus in the present embodiment offers a life protection function. In addition, the functions of the transmitting end TE**4** and the receiving end TE**2** are not limited to those described in the present embodiment, and other possible states (for example, any malfunction or the charge status of the energy transmitter **803**) of the energy transmitter **803** and the energy receiver **804***a* may be shared between the transmitting end TE**4** and the receiving end TE**2**.

Referring to FIG. **8**B, in another embodiment, the transmitting end TE**1** of the energy transmitter **803** may also be a fiber optic connector. In other words, the energy transmitter **803** may be considered a charging station with a fiber optic connector. Thus, the energy transmitter **803** is connected to the energy receiver **804***a* through optical fiber to transmit light energy. After that, the energy receiver **804***a* converts the light energy into the second electric energy EP2 to be consumed by the external apparatus **806***a*.

FIG. **11** is a diagram illustrating a charge apparatus driven by a natural energy according to a seventh exemplary embodiment of the present disclosure.

Referring to FIG. **11**, the natural-energy-driven charge apparatus in the present embodiment includes a natural energy conversion module **900**, a plurality of energy converters **902**, a plurality of energy transmitters **903**, and an energy receiver **904***a*. The natural energy conversion module **900** includes a plurality of conversion units **900***a*, **900***b*, and **900***c*.

In the present embodiment, the conversion units **900***a*, **900***b*, and **900***c* convert a natural energy N**1** into a first electric energy EP**1**, and the conversion units **900***a*, **900***b*, and **900***c* may be photovoltaic cells. The charge apparatus in the present embodiment is similar to the charge apparatus in the sixth embodiment, while the main difference between the two is that each of the conversion units **900***a*, **900***b*, and **900***c* has a corresponding energy converters **902***a*, **902***b*, or **902***c* and a corresponding energy transmitters **903***a*, **903***b*, or **903***c*. The energy converters **902***a*, **902***b*, and **902***c* convert the first electric energy EP**1** into a wireless energy W. The energy transmitters **903***a*, **903***b*, and **903***c* receive the wireless energy W and transmit it to the energy receiver **904** in a wireless manner.

To be specific, when the energy converters **902***a*, **902***b*, and **902***c* convert the first electric energy EP**1** into the wireless energy W (for example, an electromagnetic wave energy), the energy transmitters **903***a*, **903***b*, and **903***c* transmit the wireless energy W to the energy receiver **904** in a wireless manner. In the present embodiment, to increase the wireless transmission efficiency, the energy receiver **904** includes an energy receiving head **904***a*. In the present embodiment, a receiving surface of the energy receiving head **904***a* is in a cone shape. However, in other embodiments, the receiving surface of the energy receiving head **904***a* may also be in a parabolic shape, an elliptical shape, a hemispherical shape, a funneled shape, a bowl shape, a disc shape, or any other shape that can increase the receiving efficiency. For example, in another embodiment, the energy receiver **904** may be an antenna, such as a dipole antenna, a panel antenna, a microstrip antenna, a multiple element dipole antenna, a Yagi antenna, a parabolic dish, an omniantenna, a grid antenna, or a disc antenna.

As shown in FIG. **11**, because the energy receiver **904** in the present embodiment has the energy receiving head **904***a*, the wireless energy W transmitted by the energy transmitters **903***a*, **903***b*, and **903***c* from different directions can be simultaneously received. In addition, an electricity storage device **905** may be connected to the energy receiver **904** externally. After the energy receiver **904** converts the wireless energy W into the second electric energy EP**2**, the second electric energy EP**2** may be stored into the electricity storage device **905** and then a determination for determining whether to transmit the second electric energy EP**2** to an external apparatus **906***a* to charge the same according to the actual requirement is performed.

In another embodiment, the energy receiver **904** may be implemented as a rotary energy receiver such that the receiving angle can be adjusted according to the positions of the energy transmitters **903***a*, **903***b*, and **903***c*. For example, the energy receiving head **904***a* can rotate to sequentially receive the wireless energy W emitted by the energy transmitters **903***a*, **903***b*, and **903***c* from different directions. In other embodiments, the energy transmitters **903***a*, **903***b*, and **903***c* may be disposed in different power plants, and the energy receiver **904** may be disposed on the top of a building along with the electricity storage device **905**, so that the energy receiver **904** can receive the wireless energy W from the power plants, convert the wireless energy W into the second electric energy EP**2**, and store the second electric energy EP**2** into the electricity storage device **905** or supply the second electric energy EP**2** to the residents in the building.

Additionally, in the present embodiment, the conversion units **900***a*, **900***b*, and **900***c* are all solar panels. However, in another embodiment, the conversion units **900***a*, **900***b*, and **900***c* may also be wind power plants, geothermal power plants, or hydraulic power plants.

Moreover, as shown in FIG. **12**, in another embodiment, the conversion unit **900***a* may also be disposed in the space to directly collect solar energy (i.e., the natural energy N**1**). For example, a solar panel **908** that has a surface area of up to several square kilometres can be deployed on a synchronous orbit outside the aerosphere of the Earth **907** for collecting the more intensive solar energy N**1** compared to that collected on the ground. Then, the solar energy N**1** is transmitted back to the energy receiver **904** (illustrated in FIG. **11**) on the Earth **907** through laser or microwave, and the energy receiver **904***a* may be a giant disc antenna located within a prohibited area on the sea or a reservoir.

FIG. **13** is a diagram illustrating how an energy transmitter transmits a wireless energy to an energy receiver according to another exemplary embodiment of the present disclosure.

As shown in FIG. **13**, in the present embodiment, the energy transmitter **803'** transmits the wireless energy W through a magnetic field M**1**. To be specific, the energy transmitter **803'** converts the first electric energy EP**1** received from the energy converter **802** (illustrated in FIG.

8A) into a magnetic energy **M1** and radiates it into the space. The external apparatus **806***a* receives the magnetic energy **M1** through an energy receiver **804'** and converts the magnetic energy **M1** into the second electric energy EP**2** to be consumed by the external apparatus **806***a*. In addition, the energy receiver **804'** may also be a multipolar receiver having multiple magnetic poles. Namely, the energy receiver **804'** is a receiver with multiple N/S polarity combinations such that the magnetic energy **M1** in the space can be effectively collected and converted into the second electric energy EP**2** to be consumed by the external apparatus **806***a*.

FIG. **14** is a diagram illustrating how an energy transmitter transmits a wireless energy to an energy receiver according to another exemplary embodiment of the present disclosure.

As shown in FIG. **14**, besides that the external apparatus **806***a* receives the wireless energy W from the energy transmitter **803** and the energy receiver **804***a* converts the wireless energy W into the second electric energy EP**2**, as illustrated at the lower part of the FIG. **14**, when the energy transmitter **803** stops transmitting energy, if the energy receiver **804***a* is located within the transmission environment of other wireless energy (for example, light energy, radio wave, or solar energy), the energy receiver **804***a* directly converts the natural energy N**1** (for example, the solar energy) into the second electric energy EP**2** to be consumed by the external apparatus **806***a* by using an auxiliary natural energy conversion module **808**. The auxiliary natural energy conversion module **808** may be a solar panel disposed on the energy receiver **804***a*.

Moreover, the energy receiver **804***a* may have a general receptacle, and when the supply of the natural energy N**1** stops, energy can still be supplied to the external apparatus **806***a* through the receptacle or a battery. As described above, the energy receiver **804***a* in the present embodiment is a multifunctional apparatus.

FIG. **15** is a block diagram illustrating a charge apparatus driven by a natural energy according to another exemplary embodiment of the present disclosure. The natural-energy-driven charge apparatus in the present embodiment includes an energy end, a transmitting end, a receiving end, and a user end. The energy end may be an energy conversion module **1100**, and the energy conversion module **1100** receives an energy P, converts the energy P into a first electric energy EP**1**, and transmits the first electric energy EP**1** to the transmitting end, wherein the energy P may be a natural energy, the mains electricity, or other energies. The transmitting end includes an energy converter **1200** and an energy transmitter **1300**. The energy converter **1200** converts the first electric energy EP**1** into a wireless energy W and transmits the wireless energy W to the energy transmitter **1300**.

In the present embodiment, the energy transmitter **1300** includes a transmitter **1310**, an energy splitting device **1320**, a position sensor **1330**, and a message receiver **1340**. The transmitter **1310** transmits the wireless energy W to the receiving end in a wireless manner. The wireless transmission may be achieved through electromagnetic induction, microwave, or light energy, wherein electromagnetic induction has shorter transmission distance but is easier to implement and safer to human health.

In addition, the energy splitting device **1320** allows the energy transmitter **1300** to transmit different portions of the wireless energy W to a plurality of receiving ends. As shown in FIG. **15**, the receiving end may be an energy receiver **1400**, and the energy receiver **1400** includes a receiver **1410** and a converter **1420**. The receiver **1410** receives the wireless energy W and transmits it to the converter **1420** in a wireless manner. The converter **1420** converts the wireless energy W into a second electric energy EP**2** to be consumed by an external apparatus. Herein the external apparatus may be an apparatus circuit **1510** or an energy storage apparatus **1520** at the user end, wherein the energy storage apparatus **1520** may be an electricity storage device deployed on the top of a building to be used by residents in the building.

The energy receiver **1400** further includes a controller **1430**, a feedback apparatus **1440**, and a positioning apparatus **1450**. The positioning apparatus **1450** sends a displacement signal S to the energy transmitter **1300** to allow the energy transmitter **1300** to adjust the transmission direction of the wireless energy W. The controller **1430** controls the feedback apparatus **1440** and the positioning apparatus **1450** according to an information D of the receiver **1410**, wherein the information D may be the status of the wireless energy W currently received by the receiver **1410**. When the controller **1430** detects that the intensity of the wireless energy W received by the receiver **1410** is lower than a predetermined threshold, the feedback apparatus **1440** and the positioning apparatus **1450** that receive a control signal CS**2** send an instruction signal S to the position sensor **1330** and the message receiver **1340** at the transmitting end. Then the controller **1350** at the transmitting end adjusts the energy distribution quantity of the energy splitting device **1320** or the transmission position or direction of the energy transmitter **1300**, so as to allow the receiver **1410** at the receiving end to receive a more intensive wireless energy W. On the other hand, a position sensor **1330** and the positioning apparatus **1450** may communicate with each other through microwave in a single direction or in two different directions between the transmitting end and the receiving end to determine the exact position of the receiving end. Moreover, similar to that in the embodiment described above, the natural-energy-driven charge apparatus in the present embodiment also offers the charge status detecting and obstacle monitoring functions such that the power consumption can be reduced and human safety can be protected. The present embodiment can be referred to related description of foregoing embodiments therefore will not be described herein.

In summary, a natural-energy-driven charge apparatus provided by the present disclosure can convert a natural energy into electric energy, and therefore is very economical and environment-friendly. Besides, the natural-energy-driven charge apparatus provided by the present disclosure can control the charge status of a charged apparatus. In addition, in a natural-energy-driven charge apparatus provided by the present disclosure, the electric energy is converted into an electromagnetic wave by an electrically-driven energy transmitter, and the electromagnetic wave is received and stored as electric energy by an energy receiver, so that the effect of conventional energy charging through power cable is achieved. Thus, the problems of oxidized contact point, power failure, and electromagnetic interference in the existing contact charging technique are prevented, and the problem of tangled cables when different electronic products are used can be avoided. Moreover, in the natural-energy-driven charge apparatus provided by the present disclosure, no additional circuit is required for connecting the energy transmitter and the energy receiver so that the application of the natural-energy-driven charge apparatus is not limited by its working environment.

It will be apparent to those skilled in the art that various modifications and variations can be made to the structure of the disclosed embodiments without departing from the scope or spirit of the disclosure. In view of the foregoing, it is intended that the disclosure cover modifications and variations of this disclosure provided they fall within the scope of the following claims and their equivalents.

What is claimed is:

1. A charge apparatus driven by a natural energy, comprising:
   - a natural energy conversion module receiving the natural energy and converting the natural energy into a first electric energy;
   - an energy converter, electrically connected to the natural energy conversion module to convert the first electric energy into a wireless energy;
   - an energy transmitter, electrically connected to the energy converter to transmit the wireless energy;
   - an energy receiver, receiving the wireless energy and converting the wireless energy into a second electric energy to charge at least one external apparatus, wherein the energy transmitter monitors the current charge status of the external apparatus so as to adjust transmitting the wireless energy; and
   - an electricity storage device is electrically connected to the natural energy conversion module to store the first electric energy.

2. The charge apparatus according to claim **1**, wherein the energy transmitter stops supplying the wireless energy when the external apparatus is fully charged.

3. The charge apparatus according to claim **1**, wherein a receiving angle of the energy receiver is adjusted according to the position of the energy transmitter.

4. The charge apparatus according to claim **1**, wherein the energy receiver has an energy receiving head to rotate to receive the wireless energy.

5. The charge apparatus according to claim **1**, wherein the wireless energy comprises at least one of a magnetic energy and an electromagnetic wave.

6. The charge apparatus according to claim **5**, wherein the electromagnetic wave is a microwave, a light wave, a radio wave, or a laser.

7. The charge apparatus according to claim **1**, wherein the energy transmitter comprises a position sensor for detecting a position of the energy receiver.

8. A charge apparatus driven by a natural energy, comprising:
   - a natural energy conversion module, receiving the natural energy and to convert the natural energy into a first electric energy;
   - an energy converter, electrically connected to the natural energy conversion module to convert the first electric energy into an electromagnetic wave;
   - a transmitting antenna, electrically connected to the energy converter to transmit the electromagnetic wave in a wireless manner;
   - a receiving antenna, receiving the electromagnetic wave in a wireless manner to convert the electromagnetic wave into a second electric energy to charge an external apparatus, wherein the transmitting antenna monitors the current charge status of the external apparatus so as to adjust transmitting the electromagnetic wave; and
   - an electricity storage device is connected to the receiving antenna to store the second electric energy.

9. The charge apparatus according to claim **8**, wherein the charge apparatus further comprises a position sensor.

10. The charge apparatus according to claim **8**, wherein the transmitting antenna stops supplying the electromagnetic wave when the external apparatus is fully charged.

11. The charge apparatus according to claim **8**, wherein a receiving angle of the receiving antenna is adjusted according to the position of the transmitting antenna.

12. The charge apparatus according to claim **8**, wherein the receiving antenna has a receiving head to rotate to receive the electromagnetic wave.

13. A charge apparatus driven by a natural energy, comprising:
   - an energy receiver receiving a wireless energy and converting the wireless energy into a second electric energy; and
   - an external apparatus is charged by the energy receiver wherein a charge status of the external apparatus is monitored so as to adjust the wireless energy transmitting.

14. The charge apparatus according to claim **13**, wherein the energy receiver has an energy receiving head which rotates to receive the wireless energy.

15. The charge apparatus according to claim **13**, wherein the charge apparatus, further comprising:
   - a natural energy conversion module receiving the natural energy and converting the natural energy into a first electric energy;
   - an energy converter, electrically connected to the natural energy conversion module to convert the first electric energy into a wireless energy;
   - an energy transmitter, electrically connected to the energy converter to transmit the wireless energy; and
   - an electricity storage device is electrically connected to the natural energy conversion module to store the first electric energy.

16. The charge apparatus according to claim **15**, wherein the energy transmitter stops supplying the wireless energy when the external apparatus is fully charged.

17. The charge apparatus according to claim **15**, wherein a receiving angle of the energy receiver is adjusted according to the position of the energy transmitter.

(57) **ABSTRACT**

Disclosed are various embodiments for energy harvesting by circuitry of a node in a network. The node operates in a communication mode that includes communicating, via an RF transceiver, data with another node in the network. The node includes an energy storage device that provides power for the node. The node switches, via an RF switch, from said communication mode to an energy harvest mode. The energy harvest mode includes receiving RF emissions accessible to the node via an antenna. The RF emissions are converted to DC electrical energy, and the DC energy is stored in the energy storage device.

FIG. 5

RF ENERGY HARVESTING BY A NETWORK NODE

BACKGROUND

A communications module for a gas or water meter (or any other battery-powered utility device) must be able to support a battery life of 15-20 years. This is primarily achieved through the use of efficient energy-storage batteries as well as by minimizing the power consumption of the communications module (radio). In order to minimize power consumption, the radio may spend most of its time in a low-power "sleep" mode, waking up on some periodic basis to communicate any data with its network and then returning to sleep.

Replacing exhausted batteries in numerous such devices deployed in operation is a time-consuming and difficult task. Increasing the usable life-span of the batteries in these metering devices can produce significant savings in time and money for utility operators.

SUMMARY

Various aspects of the present invention relate to capturing ambient radio frequency (RF) emissions in order to supplement the energy stored by a node, such as a utility meter that may be deployed as part of an advanced metering infrastructure (AMI) system. In one implementation, the node operates in a communication mode that includes communicating, via an RF transceiver, data with another node in the network. The node includes an energy storage device, such as a battery, that provides power for the node. In various embodiments, the node may not be connected to an external source of power.

The node uses an RF switch in order to switch from the communication mode to an energy harvest mode. The mode switch may occur as a result of the node also entering a low-energy sleep mode and/or having no additional data to be communicated via the network. The energy harvest mode includes receiving RF emissions accessible to the node via an antenna and does not attempt to decode the RF emissions. The node converts the RF emissions to direct current (DC) energy and stores the DC energy in the energy storage device. The RF emissions may be converted to DC energy using a rectifier. The node may switch back to the communication mode based in part upon having data to be transmitted, data scheduled to be received, and/or other possible circumstances.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the present disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, with emphasis instead being placed upon clearly illustrating the principles of the disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a drawing of a networked environment according to various embodiments of the present disclosure.

FIG. **2** is a block diagram of an illustrative example of a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **3** is a flowchart illustrating one example of RF harvesting functionality implemented in a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **4** is a flowchart illustrating another example of RF harvesting functionality implemented in a node in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

FIG. **5** is a block diagram that provides another example illustration of a node employed in the networked environment of FIG. **1** according to various embodiments of the present disclosure.

DETAILED DESCRIPTION

The techniques disclosed herein are directed to a node capturing ambient RF emissions in order to supplement the energy provided to the node by an energy storage device. The node may use an antenna to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, and unlicensed industrial, scientific and medical (ISM) bands (900 MHz and 2.4 GHz). For example, research studies have shown an ambient RF energy density of between −60 and −14 dB/m^2 in typical urban environments, all within the 685 MHz to 3.5 GHz frequency range. In these studies, the most energy was found to be in the 1.8-1.9 GHz band.

A node, such as used in a meter for utility service (e.g. electricity, water or gas) as part of an AMI (advanced metering infrastructure) network, can incorporate one or more wideband antennas tuned for all or a portion of these frequency bands. The wideband antenna would collect or "harvest" the RF energy, which could then be converted to a DC electrical energy by, for example, an RF/microwave rectifier circuit. The DC output of the rectifier would then be stored in an energy storage device of the node, such as a battery or supercapacitor, via a charging circuit. The energy stored in the energy storage device would then provide DC power for the node during its operation. While the amount of energy harvested may not be equivalent to the energy consumed by the node during all stages of operation, the energy may be used to supplement the energy stored in the energy storage device.

As defined herein, a "node" includes an intelligent device capable of performing functions related to distributing messages in a mesh network. In one system, a node can be a meter located at a facility, such as a house or apartment, that measures the consumption of a utility such as gas, water, or electric power. Such a meter can be part of an RF network used for AMI. Other examples of nodes include a router, collector or collection point, host computer, hub, or other electronic device that is attached to a network and is capable of sending, receiving, or forwarding information over a communications channel.

A node can contain several components that enable it to function within implementations of the present invention. For example, a node can include a radio that can enable it to communicate with like nodes and/or other devices in the mesh network. The radio of each node may have a programmable logic controller (PLC)-like device that can enable the radio to function like a computer, carrying out computer and command functions to provide implementations of the present invention described herein. A node may also include a storage medium for storing information related to communication with other nodes. Such storage mediums can include a memory, a floppy disk, CD-ROM, DVD, or other storage devices located internal to the node or accessible by the node via a network, for example. A node may also include a crystal oscillator (i.e. a clock) to provide timekeeping and an energy storage device (e.g. a battery) to provide back-up power. Some nodes may be powered only by an energy storage device.

With reference to FIG. **1**, shown is an exemplary illustration of a mesh network that may be employed as part of an AMI or other metering network. The head-end system **103** controls the metering network by communicating through the network **106**. The network **106** that the head-end system **103** may utilize to communicate to a node **109** may include devices such as other nodes, **110-112**, collectors **115**, routers **118**, and possibly other devices. Communication may proceed utilizing any appropriate protocol and any appropriate network configuration. Protocols used by the network **106** include, but are not limited to the IEEE 802.15.4, PRIME, G3, and/or TCP/IP protocols. Several nodes **109-112** may transmit data to a router **118**. The router **118**, in turn, may route data to a collector **115** in the network **106**. A collector may receive data from multiple routers. The collector **115** communicates with the head-end system **103**. The head-end system may receive and send information to multiple collectors.

The nodes, such as the node **109**, may be meters that are usually in geographically dispersed locations such as homes or businesses. The meters are used to monitor a utility resource such as electricity, water, or natural gas and to measure the usage of the resource. Some meters may be smart meters that support a variety of service commands. These service commands may allow utilities to disconnect, or limit service remotely or manually at the meter. In addition, some meters may store an event log that contains entries of functions the meter has performed. Service commands may originate from the head-end system **103** and are sent via the network **106** to nodes **109-112**.

To support functionality and continuous operation of a meter, the node **109** may include an energy storage device either as a supplemental/backup power source or as a sole power source. In order to reduce the electrical power consumed during operation the node **109**, may use an antenna to capture the energy from ambient RF emissions **121** from various commercially used RF bands, such as cellular, broadcast television, and ISM bands. While harvesting RF emissions in this manner has the benefit of reducing electrical power consumed from other sources, it can be especially critical when the node is reliant upon an energy storage device as the only power source for an extended period.

In some embodiments, the node **109** may begin harvesting energy from the ambient RF emissions **121** during periods in which no communications are expected to occur. During such periods, a portion of the components of the node **109** may enter a low-energy "sleep" mode in order to conserve electrical power. In these embodiments, an RF switch may be used to switch the one or more antennas of the node from the transceiver circuitry to the circuitry used for RF harvesting.

In other embodiments, a node may harvest energy from the ambient RF emissions **121** independent of communications of node through the use of antenna(s) and other circuitry that is separate from the communications circuitry. In these embodiments, the RF harvesting may occur continuously or when a threshold is met associated with the energy storage device of the node (e.g. the energy level is less than 50% of capacity).

In addition, a node may communicate with other devices of the network **106** in order to request these devices to begin transmitting RF emissions in order to augment the ambient RF emissions **121** received by the node. Such a scenario would typically occur with, for example, a battery-powered node requesting that another device powered from an external source provide additional RF emissions. A request for additional RF emissions may occur, for example, when the energy storage device of the node reaches a threshold, when the ambient RF emissions **121** are insufficient, and/or based upon other criteria.

Referring next to FIG. **2**, shown is a block diagram of an illustrative embodiment of the node **109** which implements the RF harvesting techniques. The node **109** includes one or more antennas, represented by the antenna **201**, which may be used to transmit and receive communications for the node **109**, as well as capture RF emissions to be stored as energy. The design of the antenna **201** may be affected by the RF band(s) at which the node communicates in a network **106** and the RF band(s) at which the node will capture RF emissions. For example, the antenna **201** may include an antenna for the ISM 900 MHz bands, in addition to another antenna used for the 1.8-1.9 GHz RF bands.

In this illustrative embodiment of FIG. **2**, the antenna **201** is connected to an RF switch **203** that connects the antenna **201** to either the transceiver signal path or the RF harvesting signal path. As described previously, other arrangements allowing, for example, simultaneous RF harvesting and data communication may also be possible. In FIG. **2**, the transceiver signal path includes the circuitry used for communicating data to and from the node **109**, while the RF harvesting signal path includes the circuitry used to charge the energy storage device using the captured RF emissions. A node may be said to operate in a "communication mode" while the transceiver signal path is selected via the RF switch, and in an "RF harvest mode" while the RF harvesting signal path is selected.

The RF harvesting signal path comprises a rectifier **205**, charging circuitry **207**, an energy storage device **209**, and/or other components not described in detail herein. The rectifier **205** is an RF/microwave rectifier that converts the energy from the captured RF emissions as input to a DC electrical energy output. The rectifier may be implemented using, for example, diodes.

The charging circuitry **207** may adjust the voltage or other components of the DC output from the rectifier **205** to a form suitable for storing in the energy storage device **209**. The energy storage device **209** represents one or more energy storage devices such as a battery, capacitor, supercapacitor, and/or other electrical energy storage devices. In the embodiment shown in FIG. **2**, the energy storage device **209** is the only source of power for the node **109**, though other configurations that use an external power source in conjunction with a local energy storage device are possible.

A microcontroller **211** is responsible for managing the operation and data communications of the node **109**. To this end, the microcontroller **211** manages the RF switch **203** and the transceiver circuitry **213** that facilitates transmission and reception of data along the transceiver signal path. In some embodiments, the microcontroller **211** may also monitor charging of the energy storage device **209** via the charging circuitry **207**. The various components of the node **109** may receive electrical power from the energy storage device **209**. The electrical power from the energy storage device **209** may be adjusted by the voltage regulator **215** in order to accommodate the electrical needs of disparate electrical components. For example, the voltage regulator **215** may adjust the 3.0 V output from the energy storage device to the 3.45 V required by the microcontroller **211**.

Referring next to FIG. **3**, shown is a flowchart that provides an exemplary implementation of the RF harvesting operations for a method **300** of a node, such as the node **109**, according to various embodiments. It is understood that the flowchart of FIG. **3** provides merely an example of the many different types of functional arrangements that may be employed to implement the RF harvesting operations of the method **300** as described herein. The operations depicted in the flowchart of FIG. **3** illustrate the transition of the node from operating in a communication mode to operating in a harvest mode. As described previously, variations of this implementation may also be possible allowing a node to communicate via a network, while concurrently capturing energy from ambient RF emissions.

Beginning with block **303**, the node determines whether to begin the RF harvest mode or to remain in the communication mode. The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node had no current data communication taking place, nor any that were expected, some components (e.g. the transceiver circuitry) of the node might enter a low-power "sleep mode," at which time the node may also enter a harvest mode to capture RF emissions. Similarly, if the node detected that the energy level of the energy storage device was, for example, below a threshold of 50%, the node may begin RF harvesting instead of taking place in non-essential communications.

If the node determines that RF harvesting is not ready to begin, then execution of the method **300** returns to block **303**. Alternatively, if RF harvesting should be initiated, in block **306**, the node may place the RF switch in a position to provide received RF emission to the RF harvesting signal path. Thereafter, in block **309**, the node may receive RF emissions via the one or more antennas of the node. The node may use the antenna(s) to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, ISM bands (900 MHz and 2.4 GHz), and/or other possibilities. For example, research studies have shown an ambient RF energy density of between −60 and −14 dB/m2 in typical urban environments, all within the 685 MHz to 3.5 GHz frequency range. In these studies, the most energy was found to be in the 1.8-1.9 GHz band.

Next, in block **312**, the rectifier of the node converts the energy from the various received RF emissions to DC electrical energy. Then, in block **315**, the DC energy output from the rectifier may be stored in the energy storage device of the node through use of charging circuitry. The charging circuitry may be used to monitor and adjust the characteristics of the DC energy used to charge the energy storage device, monitor the current capacity of the energy storage device, and/or other possible re-charging functions. In some embodiments, some or all of the DC energy output from the rectifier may be used to directly power, at least in part, one or more other components of the node such as, for example, the microcontroller. During periods of low power usage, such as during the sleep mode, the energy collected from RF emissions may be sufficient to provide a substantial portion of the power consumed by various components (e.g. the microcontroller).

Subsequently, in block **318**, the node determines whether to continue the RF harvesting (i.e. harvest mode). The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node detected that the energy level of the energy storage device was at a threshold of 100%, the node may no longer need to continue to harvest the energy since no more capacity exists to store it. Similarly, if the node is scheduled to soon report a utility meter reading to a head-end system, the node may end the harvest mode in order to deliver the scheduled communication data.

In the event that the RF harvesting is determined to continue, execution of the method **300** returns to block **309**. Alternatively, if it is determined that the current period of RF harvesting should end, in block **321**, the node places the RF switch in a position that connects the antenna to the transceiver signal path in order to enable the node to communicate with other devices in the network. Thereafter, execution of the method **300** may return to block **303**.

Moving on to FIG. **4**, shown is a flowchart that provides another exemplary implementation of the RF harvesting operations for a method **400** of a node, such as the node **109**, according to various embodiments. It is understood that the flowchart of FIG. **4** provides merely an example of the many different types of functional arrangements that may be employed to implement the RF harvesting operations of the method **400** as described herein. The operations depicted in the flowchart of FIG. **4** illustrate the transition of the node from operating in a communication mode to operating in a harvest mode, where the node requests a neighboring node to supplement the ambient RF emissions by generating additional RF emissions to be harvested by the node. As described previously, variations of this implementation may also be possible allowing a node to communicate via network, while concurrently capturing energy from ambient RF emissions.

Beginning with block **403**, the node determines whether to begin the RF harvest mode or to remain in the communication mode. The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated.

If the node determines that RF harvesting is not ready to begin, then execution of the method **400** returns to block **403**. Alternatively, if RF harvesting should be initiated, in block **404**, the node may communicate with one or more neighboring nodes in the network to request that the node(s) produce additional RF emissions in order to supplement the energy received during the harvest mode. Typically, a node would make a request to neighboring nodes known to have an external power source (i.e. power supplied through the electric utility grid) or that otherwise have a substantial reserve of energy available.

Then, in block **406**, the node may place the RF switch in a position to provide received RF emission to the RF harvesting signal path. Thereafter, in block **409**, the node may receive RF emissions via the one or more antennas of the node. The neighboring node(s) responding to the request for addition RF emissions may produce a continuous waveform (CW) of RF energy that may be received by the requesting node, as well as other nodes in the area. The node may use the antenna(s) to capture the energy from RF emissions from various commercially used RF bands, such as cellular, broadcast television, ISM bands (900 MHz and 2.4 GHz), and/or other possibilities.

Next, in block **412**, the rectifier of the node converts the energy from the various received RF emissions to DC electrical energy. Then, in block **415**, the DC energy output from the rectifier may be stored in the energy storage device of the node through use of charging circuitry. The charging circuitry may be used to monitor and adjust the characteristics of the DC energy used to charge the energy storage device, monitor the current capacity of the energy storage device, and/or other possible re-charging functions.

Subsequently, in block **418**, the node determines whether to continue the RF harvesting (i.e. harvest mode). The determination may be made based upon the current or expected data communications with other devices in a network, a threshold in the energy storage device of the node, and/or other criteria as can be appreciated. For example, if the node detected that the energy level of the energy storage device was at a threshold of 100%, the node may no longer need to continue to harvest the energy since no more capacity exists to store it. Similarly, if the node is scheduled to soon report a utility meter reading to a headend system, the node may end the harvest mode in order to deliver the scheduled communication data.

In the event that the RF harvesting is determined to continue, execution of the method **400** returns to block **409**. Alternatively, if it is determined that the current period of RF harvesting should end, in block **421**, the node places the RF switch in a position that connects the antenna to the transceiver signal path in order to enable the node to communicate with other devices in the network. As an optional step, in block **424**, once the node has returned to the communication mode, the node may transmit a notification to the neighboring nodes indicating that the node is no longer in harvest mode and that the transmission of additional RF emission is no longer needed by the node. In some implementations, the neighboring nodes producing additional RF emissions as requested in block **404** may do so for a predefined period of time. Thereafter, execution of the method **400** may return to block **403**.

Next, in FIG. **5**, shown is another block diagram depicting an example of a node **109-112** used for implementing the techniques disclosed herein. The node **109-112** can include a processing device **502**. Non-limiting examples of the processing device **502** include a microprocessor, an application-specific integrated circuit ("ASIC"), a state machine, or other suitable processing device. The processing device **502** can include any number of processing devices, including one. The processing device **502** can be communicatively coupled to computer-readable media, such as memory device **504**. The processing device **502** can execute computer-executable program instructions and/or access information respectively stored in the memory device **504**. In some implementations, the processor **502** and memory **504** may be incorporated as components of a microcontroller, such as the microcontroller **211**.

The memory device **504** can store instructions that, when executed by the processing device **502**, cause the processing device **502** to perform operations described herein. The memory device **504** may be a computer-readable medium such as (but not limited to) an electronic, optical, magnetic, or other storage device capable of providing a processor with computer-readable instructions. Non-limiting examples of such optical, magnetic, or other storage devices include read-only ("ROM") device(s), random-access memory ("RAM") device(s), magnetic disk(s), magnetic tape(s) or other magnetic storage, memory chip(s), an ASIC, configured processor(s), optical storage device(s), or any other medium from which a computer processor can read instructions. The instructions may comprise processor-specific instructions generated by a compiler and/or an interpreter from code written in any suitable computer-programming language. Non-limiting examples of suitable computer-programming languages include C, C++, C#, Visual Basic, Java, Python, Perl, JavaScript, and the like.

The nodes **109-112** can include a bus **506** that can communicatively couple one or more components of the node **109-112**. Although the processor **502**, the memory **504**, and the bus **506** are depicted in FIG. **5** as separate components in communication with one another, other implementations are possible. For example, the processor **502**, the memory **504**, and the bus **506** can be components of printed circuit boards or other suitable devices that can be disposed in a node **109-112** to store and execute programming code.

The nodes **109-112** can also include network interface device **508**, such as may be implemented by the transceiver circuitry **213**. The network interface device **508** can be a transceiving device configured to establish one or more of the wireless communication links via an antenna **201**. A non-limiting example of the network interface device **508** is an RF transceiver and can include one or more components for establishing a communication links to other nodes **109-112** in the mesh network **106**.

Numerous specific details are set forth herein to provide a thorough understanding of the claimed subject matter. However, those skilled in the art will understand that the claimed subject matter may be practiced without these specific details. In other instances, methods, apparatuses, or systems that would be known by one of ordinary skill have not been described in detail so as not to obscure claimed subject matter.

Some portions are presented in terms of algorithms or symbolic representations of operations on data bits or binary digital signals stored within a computing system memory, such as a computer memory. These algorithmic descriptions or representations are examples of techniques used by those of ordinary skill in the data processing arts to convey the substance of their work to others skilled in the art. An algorithm is a self-consistent sequence of operations or similar processing leading to a desired result. In this context, operations or processing involves physical manipulation of physical quantities. Typically, although not necessarily, such quantities may take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared or otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to such signals as bits, data, values, elements, symbols, characters, terms, numbers, numerals, or the like. It should be understood, however, that all of these and similar terms are to be associated with appropriate physical quantities and are merely convenient labels. Unless specifically stated otherwise, it is appreciated that throughout this specification discussions utilizing terms such as "processing," "computing," "calculating," "determining," and "identifying" or the like refer to actions or processes of a computing device, such as one or more computers or a similar electronic computing device or devices, that manipulate or transform data represented as physical electronic or magnetic quantities within memories, registers, or other storage devices, transmission devices, or display devices of the computing platform.

The system or systems discussed herein are not limited to any particular hardware architecture or configuration. A computing device can include any suitable arrangement of components that provide a result conditioned on one or more function calls. Suitable computing devices include multipurpose microprocessor-based computer systems accessing stored software that programs or configures the computing system from a general-purpose computing apparatus to a specialized computing apparatus implementing one or more aspects of the present subject matter. Any suitable programming, scripting, or other type of language or combinations of languages may be used to implement the teachings contained herein in software to be used in programming or configuring a computing device.

Aspects of the methods disclosed herein may be performed in the operation of such computing devices. The order of the blocks presented in the examples above can be varied—for example, blocks can be re-ordered, combined, and/or broken into sub-blocks. Certain blocks or processes can be performed in parallel.

The use of “adapted to” or “configured to” herein is meant as open and inclusive language that does not foreclose devices adapted to or configured to perform additional tasks or steps. Additionally, the use of “based on” is meant to be open and inclusive, in that a process, step, calculation, or other action “based on” one or more recited conditions or values may, in practice, be based on additional conditions or values beyond those recited. Headings, lists, and numbering included herein are for ease of explanation only and are not meant to be limiting.

While the present subject matter has been described in detail with respect to specific aspects thereof, it will be appreciated that those skilled in the art, upon attaining an understanding of the foregoing, may readily produce alterations to, variations of, and equivalents to such aspects. Accordingly, it should be understood that the present disclosure has been presented for purposes of example rather than limitation, and does not preclude inclusion of such modifications, variations, and/or additions to the present subject matter as would be readily apparent to one of ordinary skill in the art.

Therefore, the following is claimed:

1. A method for energy harvesting by circuitry of a node in a network, comprising:

operating in a communication mode comprising:

communicating, via a radio frequency (RF) transceiver, data with another node in the network, wherein the node comprises an energy storage device that provides power for the node; and

in response to occurrence of a time period during which no further data communication is scheduled in the node, switching, via an RF switch in the node, from said communication mode to an energy harvest mode comprising:

receiving RF emissions accessible to the node via an antenna;

providing the received RF emissions to a rectifier;

converting the RF emissions to direct current (DC) energy, wherein said converting is implemented using the rectifier; and

storing the DC energy in the energy storage device.

2. The method of claim **1**, further comprising switching back to the communication mode when the node determines additional data needs to be transmitted or received by the node, the communication mode further comprising:

receiving additional RF emissions accessible to the node via the antenna; and

decoding the additional data from the additional RF emissions.

3. The method of claim **1**, wherein the node is a utility meter deployed as part of an advanced metering infrastructure (AMI) system.

4. The method of claim **1**, wherein the energy storage device is the only source of electrical power for the node during operation.

5. The method of claim **1**, wherein said switching to the energy harvesting mode is based at least in part upon the node determining that a sleep mode can begin.

6. The method of claim **1**, wherein said receiving RF emissions comprises receiving a plurality of RF signals in one or more RF bands.

7. A node, comprising:

a processor;

an antenna;

a radio frequency (RF) switch for switching connectivity to the antenna;

an energy storage device that provides power for the node;

a rectifier;

an RF transceiver for communicating on a network accessible to the node; and

a memory configured by a management application executed in the node, the management application comprising logic causing the node to:

operate in an energy harvest mode comprising:

receiving RF emissions accessible to the node via the antenna;

converting, via the rectifier, the RF emissions to direct current (DC) energy; and

storing the DC energy in the energy storage device; and

in response to occurrence of a time period during which data communication is scheduled in the node, switch, via the RF switch, from said energy harvest mode to a communication mode comprising:

communicating, via the RF transceiver, data with another node in the network, wherein said communicating uses power from the energy storage device.

8. The node of claim **7**, wherein said switch to the communication mode occurs when the node determines additional data needs to be transmitted or received by the node.

9. The node of claim **8**, wherein the additional data needs to be transmitted or received by the node on a periodic basis.

10. The node of claim **7**, wherein the management application further comprises logic to request the other node in the network to transmit additional RF emissions to the node.

11. The node of claim **7**, wherein the network is a wireless mesh network of a plurality nodes that includes the node.

12. The node of claim **7**, wherein the RF transceiver operates in one or more of the industrial, scientific and medical (ISM) RF bands.

13. The node of claim **12**, wherein said receiving RF emissions comprises receiving a plurality of RF signals in one or more RF bands, a portion of the one or more RF bands being outside the ISM RF bands.

14. A non-transitory computer-readable medium embodying a program executable by a processor of a node, comprising:

code for operating the node in a communication mode comprising:

communicating, via a radio frequency (RF) transceiver, data with another node in a network, wherein the node comprises an energy storage device that provides power for the node;

code for operating the node in an energy harvest mode comprising:

receiving RF emissions accessible to the node via an antenna;

providing the received RF emissions to a rectifier;

converting the RF emissions to direct current (DC) energy, wherein said converting is implemented using the rectifier; and

storing the DC energy in the energy storage device; and code for switching, via an RF switch in the node, between the modes based upon a determination made in the node, wherein the node switches to the energy harvesting mode in response to occurrence of a time period during which no further data communication is scheduled in the node.

15. The non-transitory computer-readable medium of claim **14**, wherein the node receives electrical power only from the energy storage device in the node.

16. The non-transitory computer-readable medium of claim **15**, wherein the program further comprises code for requesting the other node in the network to transmit additional RF emissions to the node, wherein the other node receives electrical power from an external source.

17. The non-transitory computer-readable medium of claim **14**, wherein the node is a utility meter deployed as part of an advanced metering infrastructure (AMI) system.

18. The non-transitory computer-readable medium of claim **14**, wherein the determination comprises switching to the energy harvest mode based upon a power level of the energy storage device reaching a threshold.

19. The non-transitory computer-readable medium of claim **14**, wherein the determination comprises switching to the energy harvest mode based upon a completion of a scheduled data communication.

(57) ABSTRACT

A voltage doubler rectifier RF power harvesting system is provided having at least one power harvesting module with a voltage doubler rectifier that includes a DC voltage input and output, signal input, first and second floating gate transistors that are connected in series between the DC voltage input and output, and a gate control of the floating gate is connected to a drain of the transistor. The voltage double rectifier includes a first capacitor disposed between the input signal and the drain of the first floating gate transistor, and a second capacitor disposed between a ground and the drain of the second floating gate transistor. The system includes an input antenna and a transmitter with a transmitter antenna, where a full-wave peak-to-peak voltage of an incoming RF signal is rectified. The system also includes a powered device connected to the DC voltage output to utilize the rectified signal.

RF ENERGY HARVESTING CIRCUIT

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application is cross-referenced to and claims the benefit from U.S. Provisional Patent Application 60/961,009 filed Jul. 17, 2007, and from U.S. Provisional Patent Application 60/993,260 filed Sep. 10, 2007, which are hereby incorporated by reference.

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

[0002] The present invention was supported in part by grant number DBI-0529223 from the National Science Foundation (NSF). The U.S. Government has certain rights in the invention.

FIELD OF THE INVENTION

[0003] The invention relates generally to energy harvesting. More particularly, the invention relates to the conversion of radio frequency electromagnetic power to electrical power.

BACKGROUND

[0004] Power extraction is an increasingly important technology, especially in applications relating to harvesting power from propagating radio frequency (RF) signals. RF powered devices are often used in applications where battery replacement is impossible, such as structural monitoring where the RF powered devices are embedded into a structure. Other applications for RF powered devices are in telemetry systems to remotely measure and report data back to a central processing unit, and in passive radio frequency identification (RFID) or passive RF tags to replace the bar code as a new form of data collection, where passive RFID tags are typically used in the range of 1-3 meters. Further, many modem biomedical implants are passively powered with radio waves to prolong the lifetime of the implanted device, and to reduce the chances of infection and chemical instability from the use of batteries. These biomedical implants generally operate within close proximity of the base station (typically 1-50 cm) and require robust designed since there is little tolerance for error in implanted devices. RF powered devices are also used in ultra-low power sensor networks in remote areas to eliminate the need for batteries in the sensor system to keep the sensor network free of maintenance, however they may have a backup battery in case the power provided by the RF radiation is insufficient. The applications for these sensor networks normally require an operating distance of 3 to 100 meters. Other applications for RF powered devices include access control, equipment monitoring and even personal identification.

[0005] RF powered devices require a power conversion circuit that can extract enough DC power from the incident electromagnetic waves for the passive device to operate. Far field RF powered devices are known to generally operate from distances of less than 10 meters from the RF source due to the high power loss from RF wave propagation at UHF frequencies. Other known devices achieve sufficient power but provide low output voltage with higher load current making them inadequate for use in passively powered wireless sensor networks.

[0006] For far-field RF energy harvesting applications, the RF energy is extracted from the air at a very low power density, since the propagation energy drops off rapidly as distance from the source is increased. More specifically, in free space, the electric field and power density drop off at the rate of $1/d^2$, where d is the distance from the radiating source. Here, the available power to a receiver in a far-field RF harvesting device decreases by 6 dB for every doubling of distance from the transmitter. Further, with multi-path fading, the power density drops off at a much faster rate than $1/d^2$. It is therefore critical that the power conversion circuit operate at very low receive power to achieve longer operating distance.

[0007] One of the major challenges to achieving this goal is the relatively high voltage requirement of rectifying circuits currently employed. When the available RF power to the receiver is under 100 μW, the available voltage for rectification in the RF to DC conversion system falls below 0.3V, which is much too low to overcome the threshold voltage (V_{th}) of conventional rectifier circuits. Currently, far-field RF energy harvesting circuits known in the art require a start-up circuit.

[0008] Accordingly, there is a need to develop an efficient rectifier circuit as well as improved system level design for RF to DC power conversion. What is needed is a highly efficient passive power conversion circuit for long distance passive sensing in distributed sensor networks. Further, new rectification circuits for far-field RF energy harvesting devices are needed to improve on the minimum power-threshold requirements for the system to operate. To overcome this power-threshold, significantly more efficient circuit and system level design is required over what is known in the art, especially in reducing or eliminating the need for a start-up circuit. Solutions must be found to circumvent or diminish the “dead-zone” in voltage rectification and otherwise reduce the effective threshold voltage in standard CMOS rectifier designs.

SUMMARY OF THE INVENTION

[0009] To address the current needs for a robust and efficient energy harvesting system, a voltage doubler rectifier RF power harvesting system is provided. The system includes at least one power harvesting module, where the power harvesting module has a voltage doubler rectifier structure circuit that includes a DC voltage input, a DC voltage output, a signal input, a first floating gate transistor and a second floating gate transistor, where the floating gate transistors are connected in series between the DC voltage input and the DC voltage output, and a gate control of the floating gate is connected to a drain of the transistor. The voltage double rectifier structure further includes a first capacitor disposed between the input signal and the drain of the first floating gate transistor, and a second capacitor disposed between a ground and the drain of the second floating gate transistor. The voltage double rectifier RF power harvesting system further includes a harvester antenna, where the harvester antenna is disposed to provide a signal to the signal input. Additionally included are a transmitter and a transmitter antenna, where the transmitter provides the signal for output from the transmitter antenna, and a full-wave peak-to-peak voltage of an incoming RF signal from the antenna to the signal input is rectified. The system also includes a powered device, connected to the DC voltage output to utilize the rectified signal.

[0010] In one embodiment of the current invention, the at least one power harvester further includes at least one charge storage device, where the charge storage device can include capacitors, rechargeable batteries, or non-rechargeable batteries, and the charge storage device is disposed between the voltage doubler rectifier structure and the powered device.

[0011] According to another embodiment of the invention, the at least one power harvester further includes a voltage limiting/regulation device, where the voltage limiting/regulating device is disposed between the voltage doubler rectifier structure and the powered device. Here, the embodiment can further include feedback loops where the feedback loops are feedback connections that can include the powered device to the voltage doubler rectifier structure, the powered device to the voltage limiting/regulation device, or the voltage/regulation device to the voltage doubler rectifier structure. This embodiment can also include at least one charge storage device disposed between the powered device and the voltage doubler rectifier.

[0012] According to another embodiment of the invention, the at least one power harvester further includes a power management device, where the power management device is disposed between the voltage doubler rectifier structure and the powered device. Here, the embodiment can further include feedback loops, where the feedback loops are feedback connections that can include the powered device to the voltage doubler rectifier structure, the powered device to the voltage limiting/regulation device, the powered device to the power management device, the power management device to the voltage limiting/regulation device, the power management device to the voltage doubler rectifier structure, or the voltage/regulation device to the voltage doubler rectifier structure. This embodiment can also include at least one charge storage device disposed between the powered device and the voltage doubler rectifier.

[0013] According to another embodiment, the at least one power harvester further can include an impedance matching device disposed between the harvester antenna and the voltage doubler rectifier. In this embodiment the impedance matching is an adjustable impedance matching, where the adjustment is programmable. Further, the adjustable impedance matching can be programmable.

[0014] In a further embodiment of the current invention, the at least one power harvester further includes passive components disposed between the signal input and the harvesting antenna, where a wider band match is provided along a cascade of the power harvesters.

[0015] In yet another embodiment, the floating gate transistor can be a PMOS-PMOScap, a PMOS-NMPScap, an NMOS-NMOScap, an NMOS-PMOScap, an NMOS-MiMcap, or a PMPS-MiMcap.

[0016] In a further embodiment, the harvesting antenna is a meanderline antenna, where the meanderline antenna includes an inner loop disposed between a pair of approximately matching outer loops, where the inner loop has a pair of antenna ports, and an input impedance of the meanderline antenna matches an in impedance of the voltage doubler rectifier. Here, the antenna outer loop can have a perimeter of 35 centimeters. Further, the antenna inner loop can have a perimeter to match the input impedance of the rectifier. Additionally, the antenna matching outer loops are disposed to divide the antenna into two identical parts as a virtual ground, where a fully differential signal is provided at the antenna ports.

[0017] In a further embodiment, the voltage doubler rectifier structure can be disposed in at least a two-stage rectifier cascade. According to one embodiment, the cascade is a 36-stage cascade. According to another embodiment the cascade is a 16 stage cascade.

BRIEF DESCRIPTION OF THE FIGURES

[0018] The objectives and advantages of the present invention will be understood by reading the following detailed description in conjunction with the drawing, in which:

[0019] FIG. **1**(*a*) shows a drawing of communication links between base station (hub) and passively powered sensors in a passively powered sensor network according to the present invention.

[0020] FIG. **1**(*b*) shows a diagram of an RF-DC power conversion system in a passively powered sensor according to the present invention.

[0021] FIG. **2** shows a block diagram of a passive RF-DC conversion circuit showing the equivalent circuit representation for the antenna and rectifier according to the present invention.

[0022] FIG. **3** shows a graph of the effect of impedance mismatch in high Q resonators.

[0023] FIG. **4** shows a diagram of parasitic components that affect performance of the RF-DC power conversion circuit.

[0024] FIG. **5**(*a*) shows a prior art conventional voltage doubler rectifier.

[0025] FIG. **5**(*b*) shows a diagram of a PMOS floating-gate rectifier according to the present invention.

[0026] FIG. **6** shows a diagram of a PMOS implementation of a floating gate transistor according to the present invention.

[0027] FIG. **7** shows a transistor level schematic of PMOS floating-gate rectifier according to the present invention.

[0028] FIG. **8** shows a diagram of a voltage doubler rectifier with N-stages in cascade according to the present invention.

[0029] FIGS. **9**(*a*)-(*d*) show the effect of a number of rectifier stages on (a) maximum voltage gain, (b) output DC voltage, and (c and d) input impedance of rectifier, according to the present invention.

[0030] FIGS. **10**(*a*)-(*b*) show (a) output voltage curves as function of the number of rectifier stages and the transistor width. (b) contour plot of constant output voltage according to the present invention.

[0031] FIG. **11** shows an antenna for an RF-DC converter according to the present invention.

[0032] FIGS. **12**(*a*)-(*d*) show (a) and (b) simulated and measured components of the antenna input impedance, and (c) and (d) measured input impedance of antenna and rectifier circuit according to the present invention.

[0033] FIGS. **13**(*a*)-(*b*) show (a) measured return loss, and (b) voltage gain for 36-stage rectifier design according to the present invention.

[0034] FIGS. **14**(*a*)-(*b*) show die images of (a) 16-stage rectifier circuit, and (b) 36-stage rectifier circuit fabricated in a 0.25 mm CMOS process according to the present invention.

[0035] FIGS. **15**(*a*)-(*d*) show measured output DC voltage (a) as a function of the sinusoidal input, (b) as function of input power, (c) as function of distance, and (d) measured voltage efficiency according to the present invention.

[0036] FIG. **16** shows PCB to establish performance of the RF-DC power converter at the system level according to the present invention.

[0037] FIGS. **17**(*a*)-(*f*) show measured DC output voltage (a) as function of distance and load for the 36-stage rectifier, and (b) as function of received power for the 36-stage rectifier. (c) Measured output power performance as function of distance and load for the 36-stage rectifier. (d) Measured output power as function of received power for the 36-stage rectifier. (e) Measured power conversion efficiency curves as function of distance and load for the 36-stage rectifier. (f) Measured power conversion efficiency curves as function of received power for the 36-stage rectifier according to the present invention.

[0038] FIG. **18** shows a graph of the measured energy extracted per hour as function of distance for the 36-stage rectifier according to the present invention.

[0039] FIG. **19** shows a shows a block diagram of one embodiment of the energy harvesting system according to the present invention.

[0040] FIG. **20** shows a diagram of one embodiment of a power harvester with voltage limiting/regulation, charge storage devices and power management according to the present invention.

[0041] FIGS. **21**(*a*)-(*i*) show diagrams of various feedback loops with a power harvester with voltage limiting/regulation, charge storage devices and power management according to the present invention.

[0042] FIG. **22** shows a block diagram of one embodiment of power harvester according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[0043] Although the following detailed description contains many specifics for the purposes of illustration, anyone of ordinary skill in the art will readily appreciate that many variations and alterations to the following exemplary details are within the scope of the invention. Accordingly, the following preferred embodiment of the invention is set forth without any loss of generality to, and without imposing limitations upon, the claimed invention.

[0044] The present invention is directed to systems, circuitry and techniques for obtaining, recovering, acquiring and/or harvesting electrical energy from an environment having/including radio frequency (RF) signals (for example, signals in the is a frequency or rate of oscillation within the range of about 3 Hz and about 30 GHz). The RF signals may be periodic or non-periodic. The environment is generally described as being local to the system (for example, within a radius of 40 meters, and more preferably, within a radius of 3 meters). In one embodiment, the system consists of RF power harvester circuitry to obtain, recover, acquire and/or harvest (hereinafter collectively "harvest" or the like (for example, "harvests", "harvested", "harvesting")) the RF electromagnetic waves from the environment. The RF waves may come in the form of a power transmitter or ambience RF wave. In operation, an RF signal is received by the harvester circuitry, which converts the RF signal into a voltage to be used by devices (for example, a substantially DC voltage). In one embodiment, the power harvester circuitry employs floating-gate transistors to provide improved power conversion efficiency of the system.

[0045] An RF-DC power conversion system is provided, which efficiently converts far-field RF energy to DC voltages at very low received power and voltages. Passive rectifier circuits are provided in a 0.25 μm CMOS technology using floating gate transistors as rectifying diodes. A 36-stage rectifier disclosed, according to one embodiment, can rectify input voltages as low as 50 mV with a voltage gain of 6.4 and operate with received power as low as 5.5 μW (−22.6 dBm). Implemented for far field, the circuit operates at a distance of 44 meters from a 4 W EIRP source. The high voltage range achievable at low load current, makes it practical for use in passively powered sensor networks.

[0046] The current invention provides a highly sensitive and efficient rectifier circuit and system level design for RF to DC power conversion. Fully passive rectifier circuits are provided in a 0.25 μm CMOS technology disposed to operate at very low received power. A receive antenna is provided in a 4-layer FR4 board to maximize power transfer in the system.

[0047] The harvested electrical energy can then be used to power one or more electrical devices. After RF signals are converted to DC signals, the invention can power an electrical device directly or it can incorporate other components, such as charge storage devices (e.g. batteries and capacitors), voltage limiters/regulators, power management devices, or any combination thereof. In another embodiment, the system can also incorporate feedbacks between any two or more of the components including the electrical device to be powered, the RF to DC converter, the voltage regulator, and the power management device.

[0048] When RF powered devices harvest their power from RF wave radiation, a radiating source or base station is required to transmit a high intensity RF signal wirelessly through the air. The RF signals can be within the range of about 3 Hz and about 30 GHz and may be periodic or non-periodic. The environment is generally described as being local to the system within a radius range of 3 to 40 meters.

[0049] Referring now to the figures, FIG. **1**(*a*) shows one embodiment of how the system operates as a network **100** where multiple energy harvesting systems **102** receive their energy from the same power source (shown as a hub or base station) **104**, however the RF waves **106** may also come in the form of ambient RF waves **106**. FIG. **1**(*b*) shows a diagram of an RF-DC power conversion system **108** in a passively powered sensor **102** according to one embodiment of the current invention, where the RF-DC power conversion system **108** includes an antenna **110**, connected to an integrated circuit **112**. Here, the integrated circuit **112** includes a receiver **114** and a transmitter **116**, which are connected to the antenna **110** and, optionally, to each other. The integrated circuit further includes an RF-DC converter **118** connected to the antenna **110**. According to this embodiment, the integrated circuit **112** has a holding capacitor **120** connected to the RF-DC converter **116** for receiving and holding the converted power, and providing power back to the integrated circuit **112**. Further shown is a baseband processing block **122** connected to receive a signal from the receiver **114** and connected to provide a signal to the transmitter **116**. Further, the baseband processing block **122** is connected to receive and provide signals with an electrically erasable programmable read-only memory (EEPROM) **124**. Further shown in this embodiment is an ancillary sensor **126** connected to the integrated circuit **112** through an analog to digital converter interface **128**, which may provide an additional signal for further power conversion or other sensing capabilities.

[0050] FIG. **2** shows a diagram of a passive RF-DC conversion circuit **200** showing the equivalent circuit representation for the antenna **110**, rectifier **202** and impedance matching **204**. The RF to DC power conversion system of the current invention operates in UHF frequencies in the industrial, scientific and medical bands (ISM band) of 902-928 MHz. In this frequency range, RF power is transmitted more efficiently for longer distances and experiences lower propagational losses than higher frequency bands (i.e., 2.4 GHz). The system is optimized to operate at distances above 10 meters with the capacity to store charge for long periods of time. Given that the power density drops off at the rate of $1/d^2$ in free space, the propagational RF signal loss through the air at 915 MHz can be calculated to be 51.6 dB with the Friis equation for freespace loss. The maximum transmit power allowed by the FCC in the 902-928 MHz band is 36 dBm, equivalent isotropically radiated power (EIRP) (30 dBm maximum transmit power with 6 dB antenna gain), thus the received power for distances greater than 10 meters is below 27 μW, this translates to less than 75 mV in a 50Ω matched system. The power conversion circuit must be highly sensitive for long-range operation, thus the threshold voltage of the system must be greatly reduced to improve power conversion efficiency at distances greater than 10 meters. It is also essential to come up with design techniques at the system level that can increase the voltage available for rectification to further increase the power conversion efficiency.

[0051] An RF-DC power conversion system is provided to passively amplify the voltage available for rectification by forming a high-Q resonator. The system maximizes the voltage coming into the RF-DC power conversion system **108** so that it can provide a stable DC output voltage at ultra-low receive power. The block diagram **200** of the system **108**, shown in FIG. **2**, consists of an antenna **110** to pick up the power radiated by the RF waves **106**, an impedance matching network **204** to ensure maximum power transfer in the system **108**, and a rectifier circuit **202** to convert the RF signal **106** to a DC voltage. The passive amplification of voltage is done by matching the impedances between the receive antenna **110** and the rectifier circuit **202**. Due to the high-Q nature of the voltage rectification circuit **202** (see circuit schematic in FIG. **5***b*) the impedance matching creates a high-quality factor (Q factor) resonator between the receive antenna **110** and the rectifier circuit **202**.

[0052] A key aspect to improve the efficiency of the RF-DC power conversion at the system level, according to the current invention, is to maximize the input voltage to the rectifier **202**. This is done by forming a resonator (see circuit schematic in FIG. **5***b*) with high-Q factor between the impedances of the receive antenna **110** and the rectifier circuit **202**. By doing this, it passively amplifies the incoming RF signal **106**. To ensure the maximum possible power is transferred to the rectifier circuit **202**, the impedance of the receive antenna **110** is matched to the input impedance of the rectifier circuit **202**. Due to the fact that systems with high-Q resonate with greater amplitude at the resonant frequency than systems with low-Q, the high-Q resonator acts as a passive voltage-amplifier to increase the peak voltage coming into the input of the rectifier without dissipating additional power. The passive voltage gain from the high-Q resonator is directly proportional to its Q. With an increase in the amplitude of the voltage coming to the input of the rectifier **202**, the output voltage of the rectifier **202** also increases and, therefore, increases the overall power conversion efficiency of the system **108**. One drawback of the high-Q resonator is it can reduce the operating bandwidth of the RF-DC power conversion system **108** since

$$Q = \omega \cdot \left(\frac{\text{Energy Stored}}{\text{Average Power Dissipated}} \right) \text{ or } Q = \frac{f_c}{\Delta f} \tag{1}$$

where ω is the resonant frequency in radians/second, f_c is the center frequency of operation, and Δf is the bandwidth of the system. For the far-field RF-DC power conversion system **108** operating in the band 902-928 MHz, the maximum Q that can be attained without sacrificing bandwidth is 35. This limitation on the system Q does not cause much concern since on-chip components rarely have Q of more than 10, and the parasitic resistance from these components damp out the resonator to prevent the Q of the system from limiting the bandwidth. In the case of a series connected matched LC resonator, the reactive components are complex conjugates of each other and the resistive components are matched. The Q of the resonator is therefore

$$Q = \frac{1}{2}\frac{\omega L}{R} = \frac{X_L}{2R} \text{ or } Q = \frac{1}{2}\frac{1}{\omega RC} = \frac{X_C}{2R} \tag{2}$$

where X_L and X_C are the reactive components, and R is the resistive component of the LC resonator. The Q of the resonator is half the Q of the rectifier and antenna since the resistance in the series connected matched resonator is doubled. To achieve a high system Q, it is therefore desirable to increase the reactive components of the rectifier **202** and antenna **110** while reducing resistive components.

[0053] A matching network **204** between the receive antenna **110** and rectifier **202** is necessary to fine tune the impedance match between the antenna **110** and the rectifier **202** to further reduce transmission loss and increase the voltage gain. Coarse impedance matching is done through circuit and antenna design but fine impedance matching must also be done on the PCB for more accurate matching. FIG. **3** shows a graph of the simulated effect **300** of impedance mismatch for a typical high Q resonator. The maximum voltage gain that can be attained is equal to the Q of the resonator, or half that of the rectifier Q. With impedance mismatch greater than 7%, the passive voltage gain from the resonator is reduced to below 3 regardless of the resonator Q. With impedance mismatch greater than 15%, the high-Q matching network provides no voltage gain and even yields a voltage attenuation that becomes greater with increasing Q. The impedance mismatch between the antenna and rectifier must be minimized to obtain a high voltage gain.

[0054] From the top-level diagram of FIG. **2**, the rectifier circuit is modeled by impedance with a real part R_{rect} **206** and a reactive part X_{rect} **208**. From the system point of view, the rectifier circuit **202** must be designed to reduce threshold voltage loss (V_{th}) as much as possible to improve the efficiency of the RF-DC power conversion system **108**. The rectifier circuit (see FIG. **5**(*b*)) must also be provided so that the output voltage can be scaled by cascading multiple rectifier stages in series (see FIG. **8**). Improving the Q of the rectifier input impedance is essential to increasing the power conversion efficiency of the overall system **108**. The rectifier input impedance Q should also be kept as high as possible and parasitic components in the rectifier must be kept as low as possible to maintain a high overall system Q and thus power conversion efficiency.

[0055] The number of cascaded rectifier stages (see FIG. **8**) in the RF-DC conversion system **108** also has a significant effect on the rectifier input impedance. In a conventional voltage rectification circuit design (see FIG. **5**(*a*)) in CMOS technology, the rectifier impedance as seen from the input is capacitive and resistive due to the gate capacitance and the channel resistance (r_{ds}) of the MOS transistor. In general, cascading multiple rectifier stages in series causes capacitive components to increase linearly with the number of stages, while providing parallel paths causes the resistive component to decrease. With a large number of stages, the resistive component from the rectifier is so low that it is dominated by other sources of parasitic resistance (i.e. drain and source connection resistors) and hence, the Q of the system is reduced due to the linearly increased parasitic capacitance.

[0056] Conversely, if there are too few rectifier stages in cascade, the output voltage of the rectifier may not be high enough to operate the sensor node. As the number of rectifier stages increases, the DC output voltage increases until the number of rectifier stages reaches an optimal point. Adding more stages beyond the optimal point reduces the system Q and causes a reduction in the DC output voltage. Thus, it is critical for the number of rectifier stages to be selected through thorough circuit simulation so that the output DC voltage is maximized while maintaining a high system Q to achieve maximum power conversion efficiency.

[0057] The current invention provides a reduction of the unwanted parasitic components that affect system performance. Since the system is to be designed with a high-Q resonator, any additional parasitic components between the antenna and rectifier will greatly diminish the performance of the power conversion system. It is therefore critical to specify an accurate parasitic model for simulating the effect of all parasitic components that affect power conversion efficiency. In the design of the RF-DC power conversion system, the traces connected to inputs of the rectifier are most sensitive to parasitics since a high-Q resonance is required at these inputs. For example, FIG. **4** shows an equivalent circuit model **400** for the parasitic components that affect the power conversion efficiency of the rectifier circuit.

[0058] These parasitic components cannot be avoided altogether, but the value of each parasitic component can be reduced through careful layout and package selection. The bond pad **402** can be designed to be minimum size and only consisting of the top two metal layers to reduce bond pad capacitance to the substrate. The package for the integrated circuit is selected so that pin-parasitics are minimized and critical input pins **404** are placed in locations where the length of bond wires **406** is minimized. PCB traces **408** are made as short as possible and they are impedance controlled to reduce the parasitic capacitance and inductance.

[0059] The antenna **110** structure is critical in the RF-DC power conversion system since it must extract the power radiated by the RF waves **106**. The antenna **110** performs best when it is impedance matched to the rectifier circuit **202** at the operating frequency to reduce transmission loss from PCB traces. Also, the antenna **110** must be small in area and must have a bandwidth large enough to cover the frequency band from 902-928 MHz.

[0060] FIG. **5**(*a*) shows the conventional voltage doubling rectification circuit **500**, and FIG. **5**(*b*) shows a floating-gate rectification circuit **502** according to the current invention. For the floating-gate rectification circuit **502**, floating-gate devices **504** are used to create a gate-source bias to reduce the threshold voltage loss of the MOS transistor **506**.

[0061] The voltage doubler rectifier structure is provided for the RF-DC power conversion system because it rectifies the full-wave peak-to-peak voltage of the incoming RF signal and it can be arranged in cascade to increase the output voltage. The voltage conventional doubler rectifier **500** in FIG. **5**(*a*) consists of a peak rectifier **508** formed by D_1 and C_2 and a voltage clamp **510** formed by D_2 and C_1. The voltage clamp **510** and the peak rectifier **508** are arranged in cascade configuration to provide a passive level shift in voltage before rectification.

[0062] In the negative phase of the input, current flows through diode D_2 while D_1 is cutoff. The voltage across diode D_2 stays constant around its threshold voltage and the voltage at node (1) is charged to $-V_{th2}$. At the negative peak, the voltage across capacitor C_1 is $V_{amp}-V_{th2}$, where V_{amp} is the amplitude of the input signal. In the positive phase of the input, current flows through diode D_1 while D_2 is in cutoff. The voltage across capacitor C_1 remains the same as the previous phase because it has no way to discharge. At the positive peak, the voltage across D_2 is $2V_{amp}-V_{th2}$. Since D_1 is conducting current to charge C_2, the voltage at the output is a threshold voltage below that across D_2, i.e., the voltage at the output V_{out} is $2V_{amp}-V_{th2}-V_{th1}$.

[0063] For the floating-gate rectifier circuit **502** of the current invention, the diodes D_1 and D_2 of the conventional rectifier circuit **500** are replaced by diode-tied floating gate transistors **504**. The floating gate devices **504** are provided to passively reduce the threshold voltage of the rectifier circuit **502**. In a floating gate device **504**, when charge is injected into the floating gate of the transistor **506**, it remains in the gate oxide because of the high impedance provided by the oxide layer. The gate oxide is a very good insulator, which keeps the charge from leaking off in the floating gate **504**.

[0064] To provide a floating gate device **600** in a standard CMOS process, a MOS capacitor **602** is placed in series with the gate **606** of the diode-tied transistor **604** as shown in FIG. **6**. The gate of the diode-tied transistor **606** and the MOS capacitor gate **608** are connected together to form a high impedance node to trap charges in the floating gate **610**. The charge in the floating gate **610** is therefore fixed which results in a fixed voltage bias across the MOS capacitor **602**. The charges that are trapped inside the floating gate device **600** act as a gate-source bias to passively reduce the effective threshold voltage of the transistor **604**.

[0065] The charge on the floating gate **610** can be injected via Fowler-Norheim (F-N) tunneling when the rectifier is not operating, or it can be charged by injecting a relatively large sinusoidal signal to the input of the rectifier at any time. The Fowler-Norheim tunneling technique charges the floating gate **610** to the desired voltage much faster, but the amount of charge is harder to control and also, additional circuitry is needed to inject or remove charge from the floating gate **610**. Referring again to FIG. **5**(*b*), the rectifier circuit **502** of the current invention is provided to have charge injected to the floating gate **504** with a relatively large sinusoidal input with amplitude larger than the threshold voltage of the transistor **506** used for rectification. With the large sinusoidal voltage injection, charge is injected to the floating gate **504** via the parasitic capacitance between the gate-source and gate-drain junction of the transistor **506**. With the floating-gate device **504**, the threshold voltages of the diode-tied transistors M_1 and M_2 are reduced by creating a gate-source bias. The gates of transistors M_1 and M_2 in FIG. **5**(*b*) are high impedance nodes so any charge trapped in the floating gates **504** can be retained for a long time. Retaining charge in floating-gate devices **504** is critical to the useful lifetime for the power conversion circuit in the current invention. With the 70-angstrom oxide thickness in the 0.25 μm CMOS process, the device retains charge in the floating gate **504** in excess of 10 years for normal operation at room temperature. However, the performance of the rectifier circuit **502** may reduce slightly as charge is leaked from the floating gate **504**. During fabrication, the residual charge trapped in the floating gate **504** may also affect the threshold voltage of the rectifier circuit **502**, hence the floating gate **504** must be programmed to account for these residual charges.

[0066] The transistor level schematic of the 36-stage floating-gate rectifier **700** is shown in FIG. **7**. V_{RF} represents the input signal extracted from the RF wave **106** (not shown), V_{DCin} is the input DC voltage coming from the previous rectifier stage (not shown) and V_{DCout} is the output DC voltage of the rectifier **700**. The 36-stage embodiment **700** uses diode-tied PMOS transistors **702** as rectifying devices and a MOS capacitor (MOSCAP) **704** is used to create the gate-source bias for each individual diode-tied transistor **702** in the rectifier **700**. The MOSCAPs **704** (C_{g1} and C_{g2}) generally operate in the depletion region and their capacitance is a function of the applied voltage. To create the gate-source bias, a large sinusoidal signal is applied at the input of the rectifier **700** and charge is injected over time through the parasitic capacitance of the diode-tied transistors **702**. When the gate-source bias reaches a potential close to V_{th}, the capacitance reaches a flat point and remains constant. The amount of charge stored in the floating gate **708** reaches equilibrium and the MOSCAP **704** operates in the inversion region, the source-gate bias voltage is, therefore, approximately the threshold voltage of the diode-tied transistors **702** (M_1 and M_2).

[0067] The individual stages of the floating-gate voltage doubler rectifier circuit can be arranged in cascade to increase the output voltage of the rectifier. FIG. **8** shows N stages of a voltage doubler rectifier in cascade **800**. When the rectifier stages **802** are cascaded, each rectifier stage **802** acts as a passive voltage level shifter in addition to the voltage shift in voltage clamp and peak rectification. The number of rectifier stages **602** used in the design is important since too few rectifier stages yields insufficient output voltage and too many rectifier stages damps out the effect of the high-Q resonator.

[0068] One of the important tradeoffs in the voltage doubler rectifier is the size of the transistor versus parasitic capacitance. The smaller the transistor size, the less parasitic capacitance it has, however, rectification efficiency is lowered by the smaller transistor size since smaller transistor can deliver less current to the load. The transistor sizes can be reduced to a few times the minimum width to reduce parasitic capacitance as seen from the input of the rectifier, however, the reduction in channel width may cause a decrease in the performance of the rectifier due to the increase in the channel resistance of the diode-tied transistors. As an example, two different sample designs are provided to compare the tradeoffs between a reduction in the parasitics and the rectifier performance.

[0069] The first sample design uses a relatively large device size of 12 mm/0.24 μm (NMOS) and the second uses 2 μm/0.24 μm PMOS devices. FIG. **9**(*a*) shows the maximum voltage gain that can be achieved in the rectifier with different numbers of floating-gate rectifier stages arranged in cascade. As the number of rectifier stages increase, the resonator Q between the antenna and rectifier impedance is reduced. In fact, the resonator Q is inversely proportional to the number of rectifier stages.

[0070] The output voltage of the rectifier for both designs with an input voltage with 300 mV amplitude is shown in FIG. **9**(*b*). The output voltage initially increases as more rectifier stages are added until an optimal point then it reduces as the resonator Q is decreased. The impact of the number of rectifier stages on the input impedance is shown in FIGS. **9**(*c*) and **9**(*d*). As the number of rectifier stages increase, the capacitive component in the rectifier input impedance increases thus reducing the reactive component of the rectifier input impedance. The reactive component of the rectifier input impedance is found to be inversely proportional to the number of rectifier stages. With the decrease in the reactive component, the maximum voltage gain that can be achieved at the input is also decreased at the same rate since the resistive component in the input impedance stays fairly constant. In this example, the optimized number of cascaded rectifier stages for the 12 μm (NMOS) and 2 μm (PMOS) designs is 16 and 36 stages, respectively. The simulated input impedance for the two samples is 6.6-j85Ω and 6.6-j84Ω, almost identical to each other.

[0071] To establish the tradeoff between the transistor size used for rectification versus the number of rectifier stages, a model is extracted by curve fitting of the output voltage data for the two different designs. FIG. **10**(*a*) shows a 3-dimensional surface plot for the rectifier output voltage as a function of the number of rectifier stages and the transistor width. It can be observed that a width of 2 μm is the best design choice for the highest output voltage when the number of rectifier stages is below 40. Any increase in device size from 2 μm results in a reduction in the output voltage. Reducing the device size below 2 μm could lead to a slight improvement in the output voltage. However, the number of rectifier stages required is significantly increased which results in a larger die size. FIG. **10**(*b*) shows the constant output voltage contour plot as function of the transistor width and the number of rectifier stages. The 36-stage design with a 2 μm device size is very close to the highest voltage contour, thus, this design is optimal for the output voltage.

[0072] The antenna **110** for the RF-DC conversion circuit **108** is designed with meander lines on a printed circuit board to reduce the area of the antenna **110** and to provide the desired antenna input impedance to the impedance matching network. FIG. **11** shows one embodiment of the antenna with two outer loops **1100** on each side connected to an inner loop **1102** in the center. The antenna ports **1104** are in the middle and connect to the antenna **110** through the inner loop **1102** to transform the impedance as seen from the outer loops **1100** of the antenna **110**. To achieve resonance at the desired frequency, the antenna **110** is provided to match with the input impedance of the floating-gate rectifier circuit **502**, **700**, **800**). The outer loop **1100** of the antenna **110** is designed to tune the antenna **110** to the correct operating frequency and the perimeter of the loop **1100** is 35 centimeters, roughly equal to one wavelength at 916 MHz, according to this embodiment. The perimeter of the inner loop **1102** varies depending on the value of the input impedance of the rectifier (**502**, **700**, **800**). The line of symmetry between the two sides of the antenna **110** splits the antenna **110** into two identical parts and this acts as a virtual ground to create the fully differential signal at the antenna ports **1104**. The dimension of the drawn area of the antenna is 15 cm×2 cm (6×0.8 inches). The antenna **110** is tuned for maximum received power at 916 MHz and the antenna is designed on the top layer of a 4-layer FR4 board with carefully controlled impedance to ensure the impedance of PCB traces does not vary from the intended values. According to one embodiment, the traces **1106** in the antenna **110** are exposed so that they can be tapped to fine tune the operating frequency. The impedance matching network **204**

(see FIG. **2**) can be placed anywhere along the antenna **110** to fine-tune the matching between the antenna **110** and the rectifier circuit (**502**, **700**, **800**). The antenna **110** has a bandwidth of about 40 MHz to maintain a high antenna Q. Due to the fact that the antenna **110** must be impedance matched to the rectifier (**502**, **700**, **800**), the loop configuration provides little antenna gain in the antenna **110** throughout the frequency bandwidth it operates.

[0073] FIG. **12**(*a*) shows the simulated and FIG. **12**(*b*) shows measured input impedance of the antenna **110** around the operating frequency band. The measured resistive component shows less than 1Ω variation from the simulated value and the reactive component also correlates well with the simulated results. The simulated impedance shown in FIG. **12**(*c*) and the measured input impedance shown in FIG. **12**(*d*) corresponds to the components of the receive antenna **110** for the 36-stage rectifier configuration (see FIGS. **7** and **8**). From the measurement data, the measured resistive components of the antenna **110** and rectifier (**502**, **700**, **800**) match well throughout the intended bandwidth for both embodiments. The reactive component of the 36-stage design matches at 910 MHz.

[0074] FIG. **13**(*a*) shows the plot of the return loss (S_{11}) and FIG. **13**(*b*) shows the voltage gain for the 36-stage configuration. The antenna **110** matches so that less than 1% of the transmitted signal is reflected back to the antenna (i.e. S_{11} below −20 dB) in the frequency band of operation 902-928 MHz. The configuration achieves voltage gain above 5 in a 30 MHz bandwidth, however the peak voltage gain is shifted down by approximately 10 MHz from the intended 915 MHz center frequency.

[0075] As an example of the efficacy of the current invention, rectifier devices with 16 NMOS stages and 36 PMOS stages were fabricated in a 0.25 µm 5 metal single-poly CMOS process as shown in FIGS. **14**(*a*) and (*b*), respectively. The active die areas are 350 µm×600 µm and 400 µm×1000 µm, respectively. The majority of the active area is consumed by the MOSCAPs for floating gate devices and the holding capacitors. The 16-stage and 36-stage rectifier layouts are arranged in two rows of 8 stages each, and six rows of 6 stages each, respectively. Both dies have a pair of 1-stage rectifiers included so that the functionality of the NMOS and PMOS diode-tied floating-gate devices can be individually characterized. Each rectifier is packaged in a 0.5 mm pin pitch QFN-32 package to reduce bond wire parasitics and trace lengths on the PCB.

[0076] In order to test the rectifier circuit, a small-amplitude 1 MHz sinusoidal signal is applied directly to the input. The low frequency signal minimizes parasitic effects introduced by the board as well as voltage losses in the PCB traces. FIG. **15**(*a*) shows the measured output DC voltage unloaded and with a 5 MW load for both rectifier designs as a function of the input sinusoidal amplitude, FIG. **15**(*b*). From a straight-line extrapolation of the output voltage curves, the threshold voltage for the 16-stage rectifier is 33 mV compared to 30 mV for the 36-stage rectifier. Since the difference in threshold voltages is very small between the two rectifier designs, the improvement in the output voltage of the 36-stage rectifier is primarily due to the higher number of cascaded rectifier stages used in the design.

[0077] The performance of the rectifier circuit can be specified by the sensitivity of the rectifier or the minimum input power required for voltage rectification. The average input power can be expressed as:

$$P = \frac{QV_{rms}^2}{R} = \frac{QV_{amp}^2}{2R} \tag{3}$$

where Q is the passive voltage gain from the antenna to the input of the rectifier, VMS is the input rms voltage to the rectifier, V_{amp} is the rectifier input amplitude and R is the input impedance of the rectifier circuit. The voltage gain of the 16-stage and 36-stage rectifiers, measured from the return loss of the matching between the rectifier and antenna is 4.8 and 6.4, respectively. Assuming a rectifier input impedance of 7Ω, the equivalent input power is derived and shown in FIG. **15**(*b*). In the case of the 16-stage rectifier, 2V is achieved for 80 mV input, which is equivalent to a power 20.95 µW (−16.8 dBm). Using the Friis formula for free-space wave propagation, this corresponds to an operating distance 23 meters (FIG. **15**(*c*)) assuming a 4 W radiating source. This is the maximum theoretical distance that can be achieved with this design while keeping radiated power and antenna gain under the FCC emission limit. For the 36-stage rectifier circuit, the rectifier performs better with low voltages due to the increased number of voltage doubler rectifier stages and the higher passive voltage gain. The 36-stage rectifier circuit achieves 2V for an input voltage amplitude as low as 50 mV. Using (3), these values are equivalent to 4.7 µW of power (−23.3 dBm) at 2.0 V output. In free-space, this corresponds to 49 meters in distance.

[0078] Defining the voltage efficiency as the percentage of the theoretical voltage achieved, the theoretical output for the voltage doubler architecture is the number of cascaded rectifier stages times the peak-to-peak voltage into the rectifier. In the case of the 16-stage rectifier, the theoretical output voltage is 16 times the input peak-to-peak voltage. For input voltages above 100 mV, the rectifier efficiency is over 80% as shown in FIG. **15**(*d*) and, hence, it is more efficient at higher input voltages. The voltage efficiency for the 36-stage design is higher as compared to the 16-stage rectifier design for low voltages.

[0079] To test the overall performance of the RF-DC rectifier in actual applications, a custom printed circuit board was fabricated that includes the antenna with exposed metal traces for impedance and frequency tuning as shown in FIG. **16**. The chip is directly soldered to the board and physically abuts to the antenna to minimize any stray inductance. The output DC voltage is observed via the SMA connector with an oscilloscope or a digital multimeter (DMM).

[0080] The performance of the RF-DC power conversion system can be measured wirelessly with propagating electromagnetic wave radiation. The output of an HP/Agilent 8665A signal generator is amplified by a Mini Circuits LZY-2 power amplifier to generate signals with 6 W of power in the frequency range of 902-928 MHz. The signal at the output of the power amplifier is then fed to an antenna through several series connected SMA cables. The losses in the cable combined with the return loss between the power amplifier and the transmit antenna are measured to be around 1.7 dB. Thus, the maximum radiated power is about 36 dBm (4 Watts).

[0081] Only the 36-stage rectifier design is wirelessly measured since it has superior performance in terms of received power sensitivity. Before measuring the overall performance, it is necessary to tune the frequency of the resonator circuit. The resonant frequency can be tuned to the 902-928 MHz range by placing a shorted stub tuning on the bare metal trace at the end of the antenna on the PCB. The tuning of the resonant frequency does affect the output voltage of the RF-DC conversion circuit, since the shorted stub tuning slightly modifies the physical shape of the antenna. The decrease in the output voltage is greater when the original resonant frequency is further from the desired (i.e., longer length stub tuning) band and the decrease is smaller for a resonant frequency closer to the desired band. Although the frequency tuning does affect the output voltage, this change in output voltage is much smaller compared to the change in output voltage caused by impedance mismatch. For the 36-stage rectifier design, the resonant frequency is originally 860 MHz so the size of the loop is reduced only slightly to increase the resonant frequency to 906 MHz. For the wireless measurement of the RF-DC power conversion circuit, the center frequency is set at 906 MHz for the 36-stage rectifier design.

[0082] FIGS. **17**(*a*) and (*b*) show the measured output voltage of the 36-stage rectifier as a function of distance and input power for various resistive loads. The 36-stage conversion circuit is capable of outputting DC signal levels of 2V at distances up to 15 meters with a 36 dBm radiating source when it is not loaded as shown in FIG. **17**(*a*). The measured output DC voltage decreases exponentially as distance increases and also decreases as the load resistance is decreased. With a 0.33MΩ load, the conversion circuit operates within 7 meters from the radiating source while providing 1 volt DC. From observation, the operating distance of the rectifier reduces quickly as the load current is increased while at closer distances, the dependence on load current is much less. FIG. **17**(*b*) shows the output voltage curves of the 36-stage design as function of received power calculated from the Friis equation for free-space propagation loss. The slope of the output voltage curves are relatively constant over the full range since the output voltage is inversely proportional to the log of the operating distance. The 36-stage design operates well when the received power is higher than −22 dBm.

[0083] FIG. **17**(*c*) shows the measured output power as a function of distance. The top curve represents the theoretical received power in free-space as calculated by the Friis formula for free-space propagation loss given a 36 dBm radiating source. With a 0.33MΩ resistive load, the current requirement at the load is higher so more current is drawn from the output of the rectifier to drive the load hence the curve shows a steeper slope. The slope of the roll off is directly proportional to the load current at the output of the rectifier. With a 1.32 MΩ load, 1 μW at 10 meters is possible and up to 12.3 meters with the 5.6 MΩ load. FIG. **17**(*d*) shows the output power as function of received power. From this plot, the point where the power curve starts to roll off from the straight (open circuit) line can be seen more clearly. For the 36-stage rectifier design, the output power starts to roll off at about −8 dBm for the 0.33 MΩ load, −13 dBm for the 1.32 MΩ load, and −18 dBm for the 5.6 MΩ load.

[0084] The measured power conversion efficiency versus distance curves are shown in FIGS. **17**(*e*) and (*f*). The power conversion efficiency curve for each individual load is shown as well as the maximum efficiency that can be achieved at a particular distance. For a perfectly matched resonator network, the power available for rectification is half of the received power in the antenna since only half of the power is dissipated in the rectifier. The power conversion efficiency of the RF-DC power conversion system is defined as the ratio between the DC output power and available power for rectification (half of the received power) from the antenna. The maximum efficiency measured is 60% with the 0.33 Mb load. For lower load currents, the output power is higher at longer distances so the power conversion efficiency is also sufficient at longer distances from the RF source. The configuration is most efficient at 3 meters and the power conversion efficiency curves rolls off as the inverse of distance from the RF source. The peak efficiency with the 5.6 MΩ and 1.32 MΩ load is 29% at about 9 meters and 35% at 5 meters, respectively.

[0085] FIG. **18** shows the maximum energy that can be extracted from the RF signal in one hour at various distances from the radiating source. From the logarithmic plot of extracted energy against distance, the extracted energy curve is approximately a straight line. The maximum extractable energy in an hour is 0.8 J at 1 meter, 40 mJ at 5 meters, 7 mJ at 10 meters and about 1 mJ at 15 meters from the source. With one-hour charge time, the RF-DC power conversion circuit acquires and replenishes enough energy to operate a circuit that dissipates 1 mW for one second or 100 mW for 10 ms at distances up to 15 meter. For an increase of every meter in distance, the amount of energy that can be extracted from the RF signal is reduced by a factor of 2.6. This establishes the trade off between power dissipation and operating distance of the integrated circuit powered by the RF-DC power conversion circuit.

[0086] According to one aspect of the present invention, acquiring and/or harvesting electrical energy is done from an environment having RF frequency, or rate of oscillation, within the range of about 3 Hz and about 30 GHz. The RF signals may be periodic or non-periodic. FIG. **19** shows a block diagram of one embodiment of the energy harvesting system **1900**, where the diagram shows how the RF waves **106** may come from a power transmitter **104** having a transmitter antenna **1902** however it is within the scope of the invention that the RF waves may be ambient RF waves, and be received by the energy harvester system **102**. In operation, an RF signal **106** is received by the harvester circuitry **112** (see FIG. **2**), which converts the RF signal **106** into a voltage to be used by devices **1904**, for example, a substantially DC voltage. FIG. **19** is a diagram of an RF power harvesting system **102** that harvests RF signal **104** from ambient RF energy via one or more RF signal sources **104**. The RF signal source **104** provides one or more RF signals **106**, which may be continuous or non-continuous, and/or periodic or non-periodic, and/or wideband/multi-band or narrowband, where the power transmitter **104** can be powered by a wall outlet, a battery or other power sources. The harvesting antenna **110** collects the RF signal(s) **106** and the power harvester **102** converts the RF signal(s) **106** to a DC supply. The DC voltage may be used by various devices **1902**, or stored on charge storage devices **1906**, where the charge storage device may be external or internal to the system **102**. The charge storage device **1906** stores the charge output by the power harvester **102** and, as needed, supplies the charge to the device **1904** for example, when its power dissipation exceed the power harvested by the power harvester **102**. The charge storage **1906** device may also extend the operational usage time of the device by providing extra charge.

[0087] According to one embodiment of the invention, the power harvester **102** can communicate back to the transmitter **104** via radio link or via backscattering of the incident RF wave **106**. The charge storage device may be considered external to the power harvester.

[0088] FIG. **20** is a diagram of an exemplary embodiment of a power harvester **102** with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. The antenna **110** collects the RF signal **106** (not shown), the RF-DC rectifies **118** the RF signal **106** to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Power management **1910**, in this embodiment, controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed or instructed. Charge storage **1906***c* holds the excess charge from the power harvester **102** when device is in operation and gives off charge when device is drawing more current than the power harvester circuit **112** can provide. Notably, the power management **1910** may include a switch or circuitry, which controls, monitors and/or analyzes:

[0089] (i) the power harvesting operation of the power harvester and/or components thereof, for example, the power conversion circuitry;

[0090] (ii) the operating characteristics of the power harvester and/or components thereof;

[0091] (iii) the characteristics of the output power of the power harvester, for example current; voltage and temporal characteristics thereof;

[0092] (iv) the storage operation of one or more of the charge storage devices and/or charge supplied thereto (via, for example, the power harvester); and/or

[0093] (v) the characteristics of the output power of one or more of the charge storage devices, for example, current, voltage and temporal characteristics thereof.

[0094] The voltage limiting/regulation **1908** limits the voltage that can be charged to circuits and charge storage devices **1906** to prevent it from breaking down. The voltage regulation suppresses the voltage supply voltage variation to a small range, preferably under 100 mV of variation, over wide range of temperature, supply voltage and process variations.

[0095] The power management circuitry **1910** controls the charge transfer from the power harvester **102** to the device for safe operation. The power management **1910** may turn on the conduction path for charge transfer when power at the device **1904** is needed and turns off the conduction path when power is no longer needed. The power management **1910** may connect the power harvester **102** to the external device **1904** continuously, at a regular interval, or only once, depending on the operational power requirement of the device **1904**.

[0096] FIGS. **21**(*a*)-(*f*) are diagrams of exemplary embodiments of a power harvester **102** with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. In the embodiment shown in FIG. **21**(*a*), a feedback **2100** between the device **1904** and the RF-DC power conversion **118** gives the device **1904** the control of the power harvester **102**. The feedback loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **118**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. Feedback **2100** is preferred when the RF-DC power conversion **118** requires tuning for enhanced and/or optimized matching, or when communication to the transmitter is required. The device **1904** can trigger the impedance matching network in the RF-DC **118** from matched to total mismatch. For example, this exemplary embodiment of the power harvester **102** may enable a communication link to the transmitter via backscattering of the incident RF signal. On a system where the antenna is shared, the feedback can disconnect and isolate the RFDC block from the antenna.

[0097] In the embodiment shown in FIG. **21**(*b*), the feedback **2100** between the power management **1910** and the RF-DC power conversion **118** allows the power management **1910** control of power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **118**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. This feedback configuration may be preferred when the RF-DC power conversion **118** requires tuning for enhanced and/or optimized matching that must be controlled by the power management **1910**. This configuration may be used to adjust the output voltage level of the RF-DC power conversion circuit **112**, which in turn varies the voltage at regulator output to flexibly accommodate for the voltage requirement of the device **1904**. On a system where the antenna is shared, the feedback may be employed to disconnect and isolate the RF-DC block from the antenna so it can be used for other purposes. The feedback loop **2100** can also be used for the purpose of triggering the charging the floating gate devices in certain rectifier circuits to enhance power conversion efficiency or minimize or prevent degradation in the performance of the power harvester.

[0098] FIG. **21**(*c*) shows a diagram of a power harvester **102** with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester **102** when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit **112** (not shown) can provide. The feedback **2100** between the voltage limiting/regulation **1908** and the RF-DC power conversion **118** allows the voltage limiting/regulation **1908** control of the power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **118**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. This feedback configuration is preferred when the voltage limiter/regulation **1908** needs to directly adjust the output voltage level of the RF-DC power conversion **118** to prevent the voltage regulator circuit from getting over saturated in voltage or breaking down. The configuration can be use to aid in the tuning of the impedance matching networks in the RF-DC power conversion **118**. It can also be used for the purpose of triggering the charging the floating gate devices in the rectifier circuits to enhance power conversion efficiency or prevent degradation in the performance of the power harvester.

[0099] FIG. **21**(*d*) shows a diagram another embodiment of the power harvester **102** with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. The antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester when device is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit **112** (not shown) can provide. The feedback **2100** between the device **1904** and the voltage limiting/regulation **1908** allows the device **1904** to control the regulated output voltage level of the power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the voltage limiter/regulation **1908**. It can be to select between different devices **1904** or reference voltages in the voltage limiter/regulation **1908** to robustly vary the voltage level as seen from the device **1908**. This configuration is preferred when the device does not operate on a wide range power supply and requires the voltage regulation to be very accurate, preferably to within less than 50 mV of the desire operating voltage.

[0100] FIG. **21**(*e*) shows a diagram of a power harvester with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. The antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage **1906***a* device and its output charges a different charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester **102** when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit **112** (not shown) can provide. The feedback **2100** between the power management **1910** and the voltage limiting/regulation **1908** allows power management circuits to control the regulated output voltage level of the power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the voltage limiter/regulation **1908**. It can be to select between different devices or reference voltages in the voltage limiter/regulation block to robustly vary the voltage level as seen from the device.

[0101] FIG. **21**(*f*) shows a diagram of a power harvester with voltage limiting/regulation **1908**, charge storage devices **1906** and power management **1910**. The antenna **110** collects the RF signal **106** (not shown), the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester **102** when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit can provide. The feedback **2100** between the device **1904** and the power management **1910** allows device **1904** some control of the power management circuits. The feed back loop **2100** can be used to partially or fully enabling and disabling the power management **1910**. This is desirable when the device **1904** operates frequently such that, power can be saved by turning off the power management circuit. The feedback **2100** also allows the control of how much charge is transferred from the power harvester **201** to the device **1904**.

[0102] It should be obvious that the above embodiments can be provided without the power management block **1910**, and without charge storage device **1906***c*, where the antenna **110** collects the RF signal **106** (not shown), the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage **1906***a* device and its output charges a different charge storage device **1906***b*. Without the power management circuit, the device **1904** is directly powered by the power from the voltage limiting/regulation **1908** and the charge stored on charge storage **1906***b*.

[0103] It should be obvious that the feedback **2100** provided in FIGS. **21**(*a*)-(*f*) can be applied in a similar manner without the power management block **1910**, and without charge storage device **1906***c*. The antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Without the power management **1910**, the device **1904** is directly powered by the power from the voltage limiting/regulation **1908** and the charge stored on charge storage **1906***b*. The feedback **2100** between the device **1904** and the RF-DC power conversion **118** gives the device **1904** the control the power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **118**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. This feedback **2100** configuration is preferred when the RF-DC power conversion **118** requires tuning for optimized matching or communication to the transmitter **104** (not shown) is required. The device **1904** can trigger the impedance matching network **204** (not shown) in the RF-DC **118** from matched to total mismatch. This enables a communication link to the transmitter **104** via backscattering of the incident RF signal. On a system where the antenna is shared, the feedback can disconnect and isolate the RF-DC block from the antenna.

[0104] In another embodiment provided without the power management block **1910**, and without charge storage device **1906***c* and having feedback **2100**, the antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal **106** to a DC voltage, the voltage limiter/regulator **1908** regulates the DC voltage and its output is available to an external device **1904**. The feedback **2100** between the voltage limiting/regulation **1908** and the RF-DC power conversion **118** allows the voltage limiting/regulation **1908** control of power harvester **102**. The feedback loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **1910**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. This feedback **2100** configuration may be preferred when the voltage limiter/regulation **1908** needs to directly adjust the output voltage level of the RF-DC power conversion **118** to prevent the voltage regulator **1908** from getting over saturated in voltage or breaking down. The configuration can be use to aid in the tuning of the impedance matching networks in the RF-DC power conversion **118**. It can also be used for the purpose of triggering the charging of the floating gate devices in the rectifier circuits to enhance power conversion efficiency or prevent degradation in the performance of the power harvester.

[0105] In another embodiment provided without the power management block **1910**, and without charge storage device **1906***c* and having feedback **2100**, the antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal **106** to a DC voltage, that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Without the power management circuit, the device is directly powered by the power from the voltage limiting/regulation **1908** and the charge stored on charge storage **1906***b*. The feedback between the voltage limiting/regulation **1908** and the RF-DC power conversion **118** allows the voltage limiting/regulation **1908** control of power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the RF-DC power conversion **118**. It can be used for tuning the RF-DC power conversion **118** for desirable performance and it can also be used to select between different circuit structures in the RF-DC power conversion **118**. This feedback **2100** configuration is preferred when the voltage limiter/regulation **1908** needs to directly adjust the output voltage level of the RF-DC power conversion **118** to prevent the voltage regulator circuit **1908** from getting over saturated in voltage or breaking down. The configuration can be use to aid in the tuning of the impedance matching networks in the RF-DC power conversion **118**. It can also be used for the purpose of triggering the charging of the floating gate devices in the rectifier circuits to enhance power conversion efficiency or prevent degradation in the performance of the power harvester.

[0106] In another embodiment provided without the power management block **1910**, and without charge storage device **1906***c* and having feedback **2100**, the antenna **110** collects the RF signal **106** (not shown), the RF-DC **118** rectifies the RF signal **106** to a DC voltage, that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Without the power management circuit, the device **1904** is directly powered by the power from the voltage limiting/regulation circuit **1908** and the charge stored on charge storage **1906***b*. The feedback **2100** between the device **1904** and the voltage limiting/regulation **1908** allows the device **1904** to control the regulated output voltage level of the power harvester **102**. The feed back loop **2100** can be used to partially or fully enabling and disabling the voltage limiter/regulation **1908**. It can select between different devices **1904** or reference voltages in the voltage limiter/regulation **1908** to robustly vary the voltage level as seen from the device **1904**. This configuration is preferred when the device **1904** does not operate on a wide range power supply and requires the voltage regulation to be very accurate, preferably to within less than 50 mV of the desire operating voltage.

[0107] It should be obvious that the above embodiments can be provided without the power without charge storage device **1906***c*. Charge storage after the power management block **1910** is not necessary when the conduction path between the power harvester output (not shown) and device **1904** is strongly on, and sufficient power can be delivered through this conduction path. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **188** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output charges a different charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed.

[0108] Charge storing **1906***b* after the voltage limiting/regulation **1908** is not necessary when the power management **1910** is turned on often, thus charging charge **1906***b*. The antenna **110** collects the RF signal, the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage limiter/regulator **1908** regulates the DC voltage from the charge storage device **1906***a* and its output is feeding to the power management **1910**. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester **102** when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester **102** can provide.

[0109] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***b* after regulator **1908** are possible.

[0110] Charge storage **1906***a* is not needed after the RF-DC power conversion **118** when the power received by the RF-DC power conversion **118** is stable or when the power requirement of the voltage limiting/regulation **1908** does not exceed the power harvested up to RF-DC conversion. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage and is fed directly to the voltage limiter/regulation block **1908**, the voltage limiter/regulator **1908** regulates the DC voltage from the output of RF-DC **118** and its output charges a charge storage device **1908***b*. Power management controls **1910** the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit **102** can provide.

[0111] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***a* after regulator **1908** are possible.

[0112] In cases where the device **1904** operates at peak power that does not exceed harvested power and/or the regulated power, charge storage device **1906***b* after the voltage limiter/regulator **1908** and charge storage device **1906***c* after regulation and power management **1910** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*, the voltage regulator **1908** regulates the DC voltage on charge storage **1906***a*. Power management **1910** controls the conduction path between the output of voltage regulator to device and turn on the conduction switch when power is needed at the device **1904**.

[0113] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***b* after regulator **1908** and **1906***c* after power management **1910** are possible.

[0114] In another embodiment, the charge storage devices **1906***a* and **1906***c* are not implemented. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is then applied to the voltage limiting/regulation **1908**. The voltage limiter/regulator **1908** regulates the DC voltage from the RF-DC power conversion **118** and its output charges charge storage device **1906***b*. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed.

[0115] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***a* after RF converter **118** and **1906***c* after power management **1910** are possible.

[0116] In another embodiment, the charge storage devices **1906***a* and **1906***b* are not implemented. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is then applied to the input of the voltage limiter/regulation **1908**. The voltage limiter/regulator **1908** regulates the DC voltage from the output of the RF-DC power conversion circuit **118** and its output is fed to the power management **1910**. Power management **1910** controls the conduction path between the output of voltage regulator **1908** and the device **1904**. Power management **1910** supplies power to the device **1904** when it is needed. Charge storage **1906***c* holds the excess charge from the power harvester **210** when device **1904** is in operation and gives off charge when device **1904** is drawing more current than the power harvester circuit **102** can provide.

[0117] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***a* after RF converter **118** and **1906***b* after voltage limiter/regulator **1908** are possible.

[0118] In another embodiment, the charge storage devices **1906***a*, **1906***b* and **1906***c* are not implemented. In cases that device **1904** operates once within a time interval and/or at power level lower than or equal to the harvested power from the RF environment, charge storage devices **1906***a* **1906***b* and **1906***c* are not require as part of the power harvester **102**. The antenna **101** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC voltage, the voltage regulator regulates the DC voltage from the output of RF-DC. Power management **1910** controls the conduction path between the output of voltage regulator **1908** to device **1904** and turn on the conduction switch when power is needed at the device **1904**.

[0119] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks and without charge storage **1096***a* after RF converter **118**, **1906***b* after voltage limiter/regulator **1908**, and **1906***c* after power manager **1910** are possible.

[0120] In another embodiment, the charge storage devices **1906***b* and **1906***c* are not implemented, and power management **1910** is not implemented. In cases where the device **1904** operates at peak power that does not exceed harvested power and/or the regulated power, power management **19019** and charge storage device **1906***c* and charge storage device **1906***b* after voltage regulation **1908** is not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device (charge storage **1**), the voltage regulator regulates the DC voltage on **1906***a*. The voltage regulator supplies **1908** the power directly to the device **1904**.

[0121] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***b* and **1906***c*, and power management **1910** are possible.

[0122] In another embodiment, the charge storage devices **1906***a* and **1906***c* are not implemented, and power management **1910** is not implemented. In cases that device **1904** operates once within a time interval and/or at power level lower than or equal to the harvested power from the RF environment, power management **1910** and charge storage **1906***c* after power management **1910**, and charge storage **1906***a* after RF-DC **118** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage, the voltage regulator **1908** regulates the DC voltage from the output of RF-DC **118**, that is provided to device **1904**.

[0123] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***a* and **1906***c*, and power management **1910** are possible.

[0124] In another embodiment, the charge storage devices **1906***a*, **1906***b* and **1906***c* are not implemented, and power management **1910** is not implemented. In cases that device **1904** operates once within a time interval and/or at power level lower than or equal to the harvested power from the RF environment, charge storage devices **1906***a*, **1906***b* and **1906***c* and power management **1910** is not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC voltage, the voltage regulator regulates the DC voltage from the output of RF-DC and provides it to device **1904** and turns on a conduction switch (not shown) when power is needed at the device **1904**.

[0125] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***a*, **1906***b* and **1906***c*, and power management **1910** are possible.

[0126] In another embodiment, the charge storage device **1906***b* and voltage limiter/regulator **1908** are not implemented. In cases that device **1904** operates once within a time interval and/or at power level lower than or equal to the harvested power from the RF environment, charge storage device **1906***b* is not require as part of the power harvester. The antenna collects the RF signal, the RF-DC rectifies the RF signal to a DC voltage, the voltage is provided to power manager **1910** which can store needed power in storage device **1906***c* for powering device **1904**. The power management **1910** also supplies the power directly to the device **1904**.

[0127] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***b* after voltage limiter/regulator **1908** and voltage limiter/regulator **1908** are possible.

[0128] In another embodiment, the charge storage devices **1906***b* and **1906***c*, and voltage limiter/regulator **1908** are not implemented. In cases where the device **1904** is able to tolerate wide power supply ranges, charge storage devices **1906***b* and **1906***c*, and voltage limiter/regulator **1908** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*. Power management **1910** controls the conduction path between the output of RF-DC **118** to device **1904** and turn on a conduction switch (not shown) when power is needed at the device **1904**.

[0129] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***b* after voltage limiter/regulator **1908** and charge storage devices **1906***b* after power manager **1910**, and voltage limiter/regulator **1908** are possible.

[0130] In another embodiment, the charge storage devices **1906***a* and **1906***b*, and voltage limiter/regulator **1908** are not implemented. In cases where the device **1904** is able to tolerate wide power supply ranges, charge storage devices **1906***a* and **1906***b*, and voltage regulator **1908** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC **118** rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***c*. Power management **1910** controls the conduction path between the output of RF-DC **118** to device **1908** and turn on a conduction switch (not shown) when power is needed at the device **1904**.

[0131] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***a* and **1906***b*, and voltage limiter/regulator **1908** are possible.

[0132] In another embodiment, the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** are not implemented. In cases where the device **1904** is able to tolerate wide power supply ranges, with peak power less than the harvestable energy, the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC. In this embodiment, power management **1910** may control the conduction path between the output of the RF-DC **118** to external device **1904**. The power management **1910** may responsively "turn on" the conduction when power is needed at the device **1904** or as instructed (for example, by the external device and/or other device).

[0133] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** are possible.

[0134] In another embodiment, the charge storage devices **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are not implemented. In cases where the device **1904** is able to tolerate wide power supply range, the charge storage devices **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are not require as part of the power harvester **102**. The antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC voltage that is stored on a charge storage device **1906***a*. The device **1904** is powered by the charge stored on charge storage **1906***a*.

[0135] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are possible.

[0136] In another embodiment, the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are not implemented. This embodiment can be advantageous where the external device **1904** is able to tolerate wide power supply range a, with peak power less than the harvestable energy, the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are not require as part of the power harvester **102**. In this embodiment, the antenna **110** collects the RF signal **104** (not shown), the RF-DC rectifies the RF signal to a DC. The device **1904** draws power directly from the output of RF-DC power conversion circuitry **118**.

[0137] It should be obvious that all different possible feedback **2100** configurations for power harvester **102** with feedbacks **2100** and without the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** are possible.

[0138] FIG. **22** shows a block diagram of one embodiment of power harvester, according to the current invention, where shown is the antenna **110** connected to the impedance match **204**, which is connected to the rectifier **202** of the RF-DC converter **118**. In cases where the device **1904** (not shown) is able to tolerate wide power supply range, with peak power less than the harvestable energy, the charge storage devices **1906***a*, **1906***b* and **1906***c*, and voltage limiter/regulator **1908** and power management **1910** not require as part of the power harvester. The RF signal **104** (not shown) is collected at the antenna **110** and passes through impedance matching networks **204** before reaching the rectifier **202**. In this embodiment, the impedance matching circuitry **204** may provide an enhanced and/or predetermined impedance match between the output of the antenna **110** and the input of the RF-DC converter **118**. For example, the impedance matching circuitry may be high-Q to passively increase the voltage amplitude to the rectifier or it can be low-Q to increase the bandwidth of harvestable RF signal. In certain embodiment, it may be preferred that the impedance be matched to within 5% of the ideal impedance value to achieve higher passive voltage gain from high-Q matching and higher power from low-Q matching.

[0139] The present invention has now been described in accordance with several exemplary embodiments, which are intended to be illustrative in all aspects, rather than restrictive. Thus, the present invention is capable of many variations in detailed implementation, which may be derived from the description contained herein by a person of ordinary skill in the art.

[0140] All such variations are considered to be within the scope and spirit of the present invention as defined by the following claims and their legal equivalents.

What is claimed:

1. A voltage doubler rectifier RF power harvesting system comprising:

a. at least one power harvesting module, wherein said power harvesting module comprises:
  i. a voltage doubler rectifier structure circuit, wherein said voltage doubler rectifier structure comprises:
    1. a DC voltage input;
    2. a DC voltage output;
    3. a signal input;
    4. a first floating gate transistor and a second floating gate transistor, wherein said floating gate transistors are connected in series between said DC voltage input and said DC voltage output, wherein a gate control of said floating gate is connected to a drain of said transistor;
    5. a first capacitor disposed between said input signal and said drain of said first floating gate transistor; and
    6. a second capacitor disposed between a ground and said drain of said second floating gate transistor;

b. a harvester antenna, wherein said harvester antenna is disposed to provide a signal to said signal input;

c. a transmitter;

d. a transmitter antenna, wherein said transmitter provides said signal for output from said transmitter antenna, wherein a full-wave peak-to-peak voltage of an incoming RF signal from said transmitter antenna to said signal input is rectified; and

e. a powered device, wherein said powered device is connected to said DC voltage output to utilize said rectified signal.

2. The RF power harvesting system of claim **1**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

3. The RF power harvesting system of claim **1**, wherein said at least one power harvester further comprises a voltage limiting/regulation device, wherein said voltage limiting/regulation device is disposed between said voltage double rectifier structure and said powered device.

4. The RF power harvesting system of claim **3**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

5. The RF power harvesting system of claim **3**, further comprises feedback loops wherein said feedback loops are feedback connections selected from a group consisting of said powered device to said voltage doubler rectifier structure, said powered device to said voltage limiting/regulation device, and said voltage doubler rectifier structure to said voltage limiting/regulation device.

6. The RF power harvesting system of claim **5**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

7. The RF power harvesting system of claim **1**, wherein said at least one power harvesting module further comprises a power management device, wherein said power management device is disposed between said voltage doubler rectifier structure and said powered device.

8. The RF power harvesting system of claim **7**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

9. The RF power harvesting system of claim **7**, wherein said at least one power harvesting module further comprises feedback loops wherein said feedback loops are feedback connections selected from a group consisting of said powered device to said voltage doubler rectifier structure, said powered device to said power management device, and said power management device to said voltage doubler rectifier structure.

10. The RF power harvesting system of claim **7**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

11. The RF power harvesting system of claim **1**, wherein said at least one power harvesting module further comprises a power management device and a voltage limiting/regulation device, wherein said power management device and said voltage limiting/regulation device are disposed between said voltage doubler rectifier structure and said powered device.

12. The RF power harvesting system of claim **11**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

13. The RF power harvesting system of claim **10** further comprises feedback loops wherein said feedback loops are feedback connections selected from a group consisting of said powered device to said voltage doubler rectifier structure, said powered device to said voltage limiting/regulation device, said powered device to said power management device, said power management device to said voltage limiting/regulation device, said power management device to said voltage doubler rectifier structure, and said voltage/regulation device to said voltage doubler rectifier structure.

14. The RF power harvesting system of claim **11**, wherein said at least one power harvesting module further comprises at least one charge storage device, wherein said charge storage device is selected from a group consisting of capacitors, rechargeable batteries, and non-rechargeable batteries.

15. The RF power harvesting system of claim **1**, wherein said at least one power harvester further comprises an impedance matching device disposed between said harvester antenna and said voltage doubler rectifier.

16. The RF power harvesting system of claim **15**, wherein said impedance matching is an adjustable impedance matching, wherein said adjustment is programmable.

17. The RF power harvesting system of claim **16**, wherein said adjustable impedance matching is programmable.

18. The RF power harvesting system of claim **1**, wherein said at least one power harvester further comprises passive components disposed between said signal input and said harvesting antenna, whereby a wider band match is provided along a cascade of said power harvesters.

19. The RF power harvesting system of claim **1**, wherein said floating gate transistor is selected from a group consisting of a PMOS-PMOScap, a PMOS-NMPScap, an NMOS-NMOScap, an NMOS-PMOScap, an NMOS-MiMcap, and a PMPS-MiMcap.

20. The RF power harvesting system of claim **1**, wherein said harvesting antenna is a meanderline antenna, wherein said meanderline antenna comprises an inner loop disposed between a pair of approximately matching outer loops, wherein said inner loop comprises a pair of antenna ports, wherein an input impedance of said meanderline antenna matches an in impedance of said voltage doubler rectifier.

21. The RF power harvesting system of claim **20** wherein said antenna outer loop comprises a perimeter of 35 centimeters.

22. The RF power harvesting system of claim **22** wherein said antenna inner loop comprises a perimeter to match said input impedance of said rectifier.

23. The RF power harvesting system of claim **23** wherein said antenna matching outer loops are disposed to divide said antenna into two identical parts as a virtual ground, wherein a fully differential signal is provided at said antenna ports.

24. The RF power harvesting system of claim **1**, wherein said voltage doubler rectifier structure is disposed in at least a two-stage rectifier cascade.

25. The RF power harvesting system of claim **24**, wherein said cascade is a 36-stage cascade.

26. The RF power harvesting system of claim **24**, wherein said cascade is a 16-stage cascade.

RADIO FREQUENCY ENERGY HARVESTING ENCLOSURE FOR RADIO FREQUENCY CONNECTED DEVICES

RELATED U.S. APPLICATION DATA

[0001] Provisional patent application No. 61/357,590 filed Jun. 23, 2010.

FIELD OF THE INVENTION

[0002] This invention relates to an enclosure for radio frequency (hereinafter referred to as "RF") connected devices, such as cellular phones, personal electronic tablet computers, and similar electronic devices, that contains a RF energy harvester. More particularly, this invention pertains to harvesting RF energy and converting it to direct current (hereinafter referred to as "DC") electrical energy for later use by an application circuitry located either within or on the enclosure of the RF connected device, such as displaying light-emitting images.

BACKGROUND

[0003] Radio Frequency (RF) connected devices such as cellular phones, personal electronic tablet computers, and similar devices use electromagnetic waves to communicate with base-stations that exchange information through RF energy. During such communication period, these devices send and receive RF energy to establish a communication link. This power of RF energy during communication ranges approximately from 32 μW to 1 W peak power.

[0004] It is recognized in the art that the RF energy is sometimes a health risk, and attempts have been made to limit the exposure of the user's head to RF energy. U.S. Patent Application Publication 2010/0113111, to Alfred Wong, et al., describes an apparatus to redirect RF energy from the device away from the user's head. The present invention attempts to avoid the health risks associated with RF energy by harvesting some of the RF energy and keeping it contained.

[0005] It is also recognized in the art that RF energy can be harvested and converted into DC electricity. Applications of such systems are known in biomedical implants, in order to avoid health risks associated with batteries. U.S. Patent Application Publication 2009/0152954, to Triet Tu Le, et al., describes a RF harvesting circuit with a voltage doubler rectifier circuit. The present invention obtains RF harvesting results for mobile RF connected devices.

[0006] Likewise, stylized aftermarket cellular phone cases and cases for other RF devices, such as iPod Touch® or iPad®, are popular for users to personalize their devices. The present invention supplements the options that are available to users to customize the appearance of their devices by displaying lighted images or designs. Such images or designs can also have intermittent lighting patterns according to the transmitted RF energy activity that is occurring with the device.

[0007] A primary feature of the present invention is an energy harvesting enclosure, such as a cellular phone protective case, having the ability to capture some of the transmitted RF energy, and recycle it to DC electric power, without affecting the manufacturers' intended functionality of the device operation. The harvested power and resulting voltage is derived from capturing RF energy within the existing transmitted RF field created during mobile device to base-station communication activity. Examples of base-station communication activities include, but are not limited to, incoming and outgoing calls, text messaging, and interne browsing.

[0008] Accordingly, the proposed invention harvests some of the transmitted RF energy during transmission periods while an RF connected device is in communication with a base station, and recycles it into DC power. This is accomplished in order to activate an attached or detached application circuitry. Examples of application circuitry include, but are not limited to, light-emitting devices such as light-emitting diodes, one-pixel LCD, organic LEDs, etc. Likewise, the harvested and recycled RF energy can be used to charge a storage component such as rechargeable battery or super-capacitor for a later use of the stored power.

SUMMARY OF THE INVENTION

[0009] To address the current trends of customizing and personalizing RF connected devices such as cell phones and personal electronic tablet computers, a system for harvesting RF energy and converting it into DC power to activate a light-emitting device, is provided. The system includes an enclosure for a portable RF connected device, with the enclosure comprising a first end at a first longitudinal edge of the device opposite a second end at a second longitudinal edge of the device. As well as a body section having a first side on the back of the device that is opposite the second side of the device where a screen is located. The enclosure also comprises an interior surface of the first side that is facing inward on the device toward the battery, and an exterior surface of the first side that is facing outward toward the device's outer environment. Furthermore, a RF energy harvesting antenna is located on the interior surface of the first side of the device enclosure, as well as a RF to DC power conversion circuit located on the interior surface of the first side of the device enclosure. Additionally, a conditioning circuit located on the interior surface of the first side of the device enclosure. Finally, an electric application load is located on a surface of the first side of the device enclosure. This application load is a light-emitting device. The light emitting device could be designed in such a way to depict a visual image. In addition to a light-emitting device, the enclosure of a RF connected device of is further comprising a charge storage component.

[0010] According to another embodiment of the invention, the enclosure of a RF connected device of comprises a first piece and a second piece, that mechanically fasten, with an electrical interface between the first piece and second piece. In this embodiment, the RF harvesting antenna, RF to DC conversion circuit, and conditioning circuit are located on the first piece, whereas the electric application load, in the form of a light-emitting device, is located on the second piece. The electrical interface between the first and second piece allow the RF harvesting antenna, RF to DC conversion circuit, and conditioning circuit to provide power to the application load on the second piece.

[0011] In each of the embodiments of the present invention, the RF energy harvesting multiband antenna has a an output impedance that is substantially equal to the complex conjugate input impedance of the RF to DC power conversion circuit at the center frequency of the bands of operation for the RF connected device.

[0012] Also, the RF energy harvesting multiband antenna has a surface placed at a critical distance to the metallic surface on the interior of the RF connected device. The RF energy harvesting multiband antenna is on the same plane as the device antenna, which is parallel to the broad-side, back surface of the device. If the RF energy harvesting multiband antenna is not on the same plane as the device antenna, then it is located on a plane that is within a range of 1 mm to 5 mm from the plane of the device antenna.

[0013] In any embodiment of the present invention, the RF energy harvesting multiband antenna is made of either a flexible substrate or a rigid substrate. This application is specific to the RF device design and materials.

[0014] In yet another embodiment of the present invention, the enclosure of the RF connected device comprises an intermittent flashing light-emitting device that flashes in reaction to the transmitted power level communication activities of the RF connected device.

[0015] According to a final embodiment of the present invention, there is a method for displaying light-emitting images on an enclosure for RF connected devices comprising a RF energy harvesting antenna located on an interior surface of the device enclosure, a RF to DC power conversion circuit located on the interior surface of the device enclosure, a conditioning circuit located on the interior surface of the device enclosure, and an electric application load in the form of a light-emitting device located on the exterior surface of the device enclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

[0016] FIG. **1**A shows a protective cellular phone case with a RF energy harvester antenna and application circuit located on the interior surface of the enclosure.

[0017] FIG. **1**B shows a perspective view of an exposed RF energy harvester mounted on the interior surface of the protective enclosure.

[0018] FIG. **2** shows a cross section of the of a protective cellular phone enclosure design including an embedded RF energy harvester mounted on the interior surface.

[0019] FIG. **3** shows a side view of the protective enclosure and the embedded RF energy harvester and application circuit.

[0020] FIG. **4** shows an illustration of the radio frequency energy harvester and application circuit embedded in the protective enclosure mounted on a cellular phone.

[0021] FIG. **5** shows a block diagram of the RF energy harvester and the application circuit, such as a light-emitting device.

[0022] FIG. **6** shows the electrical block diagram including voltage doubler circuit.

[0023] FIGS. **7**A & **7**B show the Smith chart plot of the multiband harvesting antenna output impedance and the RF to DC power conversion circuit input impedance on the same chart, at the PCS (1850-1910 MHz) and the Cellular (824-849 MHz) frequency bands.

[0024] FIG. **8** shows an exemplary protective enclosure comprising an interchangeable first piece that has an electrical and mechanical interface to a second piece, whereas the first piece contains a light emitting logo, or symbol on the exterior back surface of the enclosure.

[0025] FIG. **9** shows an exemplary protective enclosure for a cell phone, comprising two pieces slide-lock interface and user customizable section contain a light emitting logo, or symbol on the exterior back surface of the customizable section.

[0026] FIG. **10** shows a cell phone protective enclosure having four LEDs being activated by the RF energy harvester.

DETAILED DESCRIPTION OF THE INVENTION

[0027] The present invention is described herein with reference to a variety of RF connected device enclosures, such as those for cell phones and personal electronic tablet computers. The detailed description set forth below, in association with the drawings and diagrams, is intended as a description of exemplary embodiments of the present invention and does not represent the only embodiments in which the present invention can be practiced. The detailed description includes specific details for the purpose of providing an understanding of the present invention, and is not limiting in any way. Those skilled in the art will recognize that the invention can be practiced in various applications while deviating from the specific details described herein.

[0028] The following defined terms are of exemplary terms used within this disclosure. Except where noted otherwise, variants of all terms, including singular or plural forms, fall within each exemplary term meaning:

[0029] I. "Enclosure" as used herein means, but is not limited to the protective plastic case that is the hardware of a cellular phone, gaming device, music player, personal electronic tablet computer, etc.

[0030] II. "Radio Frequency connected" or "RF connected" as used herein, includes but is not limited to, a communicative relationship between devices or circuits via electromagnetic waves.

[0031] III. "RF to DC power conversion circuit," as used herein means a diode rectifier circuit, voltage doubler circuit, full-wave rectifier circuit, or similar solid state rectifier components and integrated circuit.

[0032] IV. "RF energy harvester," as used herein means a RF harvesting antenna and RF to DC power conversion circuit.

[0033] FIG. **1**A illustrates the interior of a RF connected device enclosure **100** with a RF harvesting antenna **101** and application circuit **102**. FIG. **1**B illustrates a RF connected device enclosure **110** made of a plastic such as ABS or similar material. RF energy is captured by means of RF harvesting antenna **111** and recycled by means of RF to DC power conversion circuit **112**. The RF energy harvester **111** and the application circuits **112** are populated on printed circuit board **113** using a thin flexible substrate or on a thin rigid printed circuit board substrate. The enclosure **110** is similar in appearance to a cellular phone external protective case.

[0034] FIG. **5** illustrates the block diagram for a RF energy harvester system. RF energy is captured by the antenna structure **501** and recycled by RF to DC power conversion circuit **502** and a power conditioning and filter circuit **503**. The combination of these blocks supply the required power to an application circuitry **504**, such as a light-emitting device. The RF to DC power conversion circuit **502** is made of small package surface mount zero bias Schottky detector diodes such as the HSMS-286x series or similar rectifier devices or integrated circuit and devices, and a filter circuit.

[0035] The application circuit **504** can be made from active devices, passive devices, or a combination of active and passive devices. Such active and passive devices include, but are not limited to, light-emitting diodes, super capacitors, solid state batteries, rechargeable batteries, and electronic circuits.

The application circuit **504** maybe embedded in the enclosure or it can be an auxiliary apparatus that is either attached or detached from the enclosure.

[0036] The presented RF energy harvester **501** does not require an impedance matching network. However, an additional impedance matching network may be utilized to broaden the impedance match of the antenna structure **501** to the RF to DC power conversion circuit **502**. The various components and structures, which are integral to the enclosure, convert mainly some of the transmitted RF energy to a DC power and voltage for activation of a single or multiple application circuits.

[0037] Several types of harvesting antenna structures **501** may be employed. A key aspect of the harvesting antenna is its impedance value. The harvesting antenna **501** impedance must be equal or near the complex conjugate impedance of that of the voltage doubler **502**, **602** input circuit, Z (Antenna) =Z*(voltage doubler), as illustrated in FIGS. 7A and 7B. The harvesting antenna **501** combined with the RF to DC power conversion circuit **502** form a resonant network.

[0038] In addition to specific antenna design practice, the embedded harvesting antenna structure is configured utilizing the enclosure material, such as ABS plastic or other enclosure material, thickness and electrical properties such as Dielectric Constant to achieve the required impedance value **701** and **703**. The embedded harvester antenna design also accounts for the distance **204** between the harvesting antenna structure **207** and the internal hardware **202** of the RF connected device. Additionally, the harvester antenna design accounts for the thickness of the enclosure material **206** that surrounds harvesting antenna structure **207**, in order to tune the harvesting antenna for optimum RF energy capturing and improve the system efficiency.

[0039] FIGS. 7A and 7B show simulated data points on a Smith Plot, of the antenna structure impedance **701**, **703** and the RF to DC power conversion circuit impedance **702**, **704** at various frequencies. In consideration of the range of frequency bands utilized for cellular phones, the harvesting antenna output impedance **701**, **703** is substantially near the complex conjugate of the RF to DC power conversion circuit input impedance **702**, **704** at the average frequency of each band.

[0040] The RF harvester employs and makes use of the RF to DC power conversion circuit **502** and the rectifier diodes junctions capacitance **602** to form the resonant circuit and impedance match **701**, **702**, such that the energy transfer to the RF to DC power conversion circuitry **502** and application circuitry **504** is optimized without the use of any matching network circuit.

[0041] Prior art teaches that an additional impedance matching circuit is required to maximize power transfer. According to the detailed description above, the present invention does not require a matching circuit to maximize power transfer, and therefore reduces the overall cost of the RF harvester. A matching network maybe used to further improve the power transfer between the harvester antenna structure and the RF to DC power conversion circuit, but is not necessary for satisfactory operation.

[0042] As illustrated in FIG. **6**, the RF to DC power conversion circuit **602** is made of a voltage doubler circuit or full wave rectifier. The output voltage can be increased by cascading more than one voltage doubler stage. The signal conditioning block **603** may include a voltage regulator and a filter circuit.

[0043] In an embodiment that employs more than one voltage doubler stage, the harvesting antenna output impedance must be tuned to the complex conjugate of the cascaded voltage doublers input impedance.

[0044] To maximize the voltage amplitude at the input of the RF to DC power conversion circuit, a virtual L-C resonant circuit is formed by the antenna inductive impedance and the RF to DC power conversion circuit diodes junctions capacitance.

[0045] The number of voltage doubler stages used has significant impact on the harvester efficiency. It will change the RF to DC power conversion circuit equivalent input capacitance. If more voltage doubler stages are used, the RF to DC power conversion circuit junction and parasitic capacitance components vary, and therefore effecting the impedance match and the resonance frequency. The presented patent utilizes but not limited to one voltage doubler stage as the RF to DC power conversion circuit FIG. **6**.

[0046] The application circuit and load impedance and resistance have an effect on the overall harvester efficiency. The presented enclosure is designed to accommodate the integrated harvesting antenna, RF to DC power conversion circuit, filter and power conditioning circuit, and the application circuitry. The presented methodology is an illustration of an exemplary enclosure and is general. One with skill in the art will recognize that different methodologies, combinations of elements, and materials maybe used.

[0047] The harvesting antenna structure placement, orientation, height, and position with respect to the transmitting antenna of the RF connected device, such as a cellular phone, is controlled during the design stage to maximize the energy harvested and minimize the effect on the Radio Frequency connected device mode of operation.

[0048] Shown in FIG. **2** is a cross-section view of the presented plastic enclosure **210**. The enclosure width **203** varies and could be different for each device and is designed to fit on the RF connected device just like in any typical protective case. In an exemplary embodiment, the enclosure wall thickness **201** ranges from about 1.5 mm to 2.5 mm. The enclosure's broad side thickness **209** ranges from about 2.5 mm to 4 mm including the cover layer **208**. The enclosure's broad side thickness **209** is designed to accommodate the integrated harvester and application circuit.

[0049] The presented RF to DC power conversion circuit and topology has a direct effect on the system efficiency and impedance matching. The RF to DC power conversion circuit input capacitance is used in conjunction with the antenna output inductance to form the high Q resonant circuit. The embedded harvester **207** and application circuit thickness **205** is about 1.5 mm. The exemplary distance **204** between the Radio Frequency connected device back **202** and the harvester, range from 1.5 mm to 5 mm and it's critical to the harvester antenna operation and impedance. It affects the harvester efficiency.

[0050] As illustrated in FIG. **8** and FIG. **10**, an embodiment of the presented enclosure including RF harvester pertains to a personalized and customizable protective cover for a person's RF connected device, such as a cellular phone. The enclosure **806** has an interface to lock, hold, and supply electrical power to a logo or icon **801**. The logo or icon section **801** may be of any shape, such as square, circle, or octagon. The logo or icon section **801** may incorporate any design such as a drawing, image, or symbol. The customizable protective cover **806** comprises an opening **805** to house an interchangeable logo or icon **801**. FIG. **8** shows a twist or push-to-lock design interface that incorporates a mechanical lock **802** and electrical contacts **803**. The thickness **804** of the presented enclosure varies to suit the logo or icon mechanical and electrical requirements.

[0051] FIG. **9** shows another embodiment of a two pieces slide-lock interface. The user customizable section **901** of the enclosure is inter-changeable and contains a logo, icon, or any application circuit, such as a light-emitting device. The larger enclosure section **904** contains the RF energy harvester and the power conditioning circuit. The two separate sections **901**, **904** of the enclosure join together by means of an electrical interface **903** and a mechanical interface **902**. A primary feature of the user customizable section **901** of the enclosure is the ability of customizing a single enclosure using multiple logo, icon, or design options. The RF connected device user is able to have one enclosure that is quickly modifiable and customizable. This is accomplished by replacing only the smaller section **801**, **901** containing a logo or icon with another that incorporates a different design or function. Interchangeability of the logo or icon section **801**, **901** is possible by incorporating the same mechanical interface **802**, **902** and electrical interface **803**, **903**, as the larger enclosure section **806**, **904**. Therefore, the user creates a new customized look and a new enclosure design or function without acquiring a new enclosure altogether.

[0052] The logo or icon section **801**, **901** may or may not incorporates electrical components. In one embodiment the logo or icon section **801**, **901** only incorporates the graphic design. The light-emitting device, such as an LED, is incorporated and embedded in the larger enclosure section **806**, **904**. The light-emitting device is placed in the larger enclosure section cavity **805**, and mounted between the internal hardware of the RF device and the logo or icon section **801**, **901** such that emitted light shines through the logo or icon to create an image for visual stimulation.

[0053] Likewise, it can be recognized and appreciated in an embodiment where a logo or icon is directly incorporated on a singular and unitary RF device enclosure, as apparent in FIG. **10**. In such an embodiment, the logo or icon is not interchangeable from the enclosure as a whole.

[0054] In FIG. **10** a cellular phone enclosure **1001** is embedded with light-emitting diodes (LEDs) **1003**. The LED excitation and illumination is facilitated through the harvested energy, without the use of a battery or any form of plugged or wired power source. The enclosure **1001** may include single or multiple antenna structures, RF to DC power conversion circuits, storage devices such as super-capacitor, electronics devices, and integral LED(s) **1003** as visual signaling devices. The light-emitting diodes **1003** are suitable for visual signaling of an incoming communication, such as phone calls or text messages, when the cellular phone is screen side down and the ringer is turned off. Likewise, the illuminated LEDs **1003** provide visual stimulation of their own as in FIG. **10** or through illuminating art such as an icon or logo **801**, as in FIG. **8**. The illumination can be constant light, or flashing light that is synchronized to the cellular phone base-station communication activities of the attached RF connected device.

[0055] Where the RF energy harvester is used to directly power the LED(s) **1003** to decorate a protective case logo or icon **801**, the RF connected device transmitted power levels and operation modes affect the brightness level of the LED(s) **1003** and is an indication of the transmitted power level. Light-emitting diode **1003** brightness is directly proportional to the peak power level of the radio frequency wave being transmitted by the Radio Frequency connected device. In another embodiment where conditioning circuit and charge storage device is used, the brightness level of the LED(s) is controlled.

[0056] In any every embodiment of the present invention, all or some of the electronic circuitry, including the logo or icon embedded circuitry, will be powered by the RF energy harvester which is incorporated and integrated within the physical structure of the RF device protective enclosure.

[0057] The logo or icon section **801**, **901** may includes batteries to power additional electronic circuitry that is triggered and controlled by the enclosure energy harvester signal and circuit. Furthermore, audible and tactile notification mechanisms, such as the ringer and vibration, can be turned of and the user will be alerted of incoming communications utilizing only the RF harvested energy to activate its integral light-emitting device on the enclosure. An obvious benefit of such method of operation results in an extension of the internal battery cycle life for the RF connected device, while continuously indicating operation of the attached device.

What is claimed is:

1. An enclosure for a portable RF connected device, the enclosure comprising:

a first end at a first longitudinal edge of the device opposite a second end at a second longitudinal edge of the device;

a body section having a first side on the back of the device that is opposite the second side of the device where a screen is located;

an interior surface of the first side that is facing inward on the device toward the battery;

an exterior surface of the first side that is facing outward toward the device's outer environment;

a RF energy harvesting antenna located on the interior surface of the first side of the device enclosure;

a RF to DC power conversion circuit located on the interior surface of the first side of the device enclosure;

a conditioning circuit located on the interior surface of the first side of the device enclosure; and

an electric application load located on a surface of the first side of the device enclosure.

2. The enclosure of a RF connected device of claim **1**, further comprising a light-emitting device on the exterior surface.

3. The enclosure of a RF connected device of claim **2**, further comprising a visual image on the exterior surface of the first side of the device enclosure.

4. The enclosure of a RF connected device of claim **1**, further comprising a charge storage component.

5. The enclosure of a RF connected device of claim **1**, further comprising:

a first piece and a second piece, that mechanically fasten;

an electrical interface between the first piece and second piece;

the RF harvesting antenna, RF to DC power conversion circuit, and conditioning circuit located on the first piece;

the electric application load located on the second piece;

the electrical interface between the first and second piece allow the RF harvesting antenna, RF to DC conversion circuit, and conditioning circuit to provide power to the application load on the second piece.

6. The enclosure of a RF connected device of claim **1**, further comprising an embedded RF energy harvesting multiband antenna having an output impedance that is substantially equal to the complex conjugate input impedance of the RF to DC power conversion circuit at the center frequencies of the bands of operation for the RF connected device.

7. The enclosure of a RF connected device of claim **5**, further comprising a RF energy harvesting multiband antenna located on the interior of the RF connected device that has a surface placed at a critical distance to the metallic surface of the internal hardware of the RF connected device, said distance in the range of 1.5 mm to 5 mm.

8. The enclosure of a RF connected device of claim **1**, further comprising a RF energy harvesting multiband antenna made of a flexible substrate.

9. The enclosure of a RF connected device of claim **1**, further comprising a RF energy harvesting multiband antenna made of a rigid substrate.

10. The enclosure of a RF connected device of claim **1**, further comprising an intermittent flashing light-emitting device synchronized by the transmitted power level of communication activities.

11. A method for displaying light emitting images on an enclosure for RF connected devices comprising:

a RF energy harvesting antenna located on an interior surface of a first side of the device enclosure;

a RF to DC power conversion circuit located on the interior surface of the first side of the device enclosure;

a conditioning circuit located on the interior surface of the first side of the device enclosure; and

an electric application load located on the exterior surface of the first side of the device enclosure.

(57) **ABSTRACT**

Disclosed is an apparatus for an application including a core device for the application. The apparatus includes a power (preferably RF energy) harvester connected to the core device to power the core device. Also disclosed is a method for an application. The method includes the steps of converting RF energy into usable energy. There is the step of powering the core device with the usable energy.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to and is a continuation application of U.S. patent application Ser. No. 12/499,618, filed Jul. 8, 2009, which is a divisional application of U.S. patent application Ser. No. 11/447,412, filed Jun. 6, 2006, which claims priority to U.S. Provisional Patent Application No. 60/688,587, filed on Jun. 8, 2005; each of which is incorporated herein by reference in its entirety.

BACKGROUND

[0002] The present invention is related to the wireless powering of devices. More specifically, the present invention is related to the wireless powering of devices with a power harvester.

[0003] As processor capabilities have expanded and power requirements have decreased there has been an ongoing explosion of devices that operate completely independent of wires or power cords. These "untethered" devices range from cell phones, and wireless keyboards to building sensors and active RFID tags.

[0004] Engineers and designers of these untethered devices continue to have to deal with the limitations of portable power sources, primarily batteries as the key design parameter. While performance of processors and portable devices have been doubling every 18-24 months driven by Moore's law, battery technology in terms of capacity has only been growing at measly 6% per year. Even with power conscious designs and the latest in battery technology, many devices do not provide the lifetime cost and maintenance requirements for applications that require a large number of untethered devices such as logistics, and building automation. Today's devices that need two-way communication require scheduled maintenance every three to 18 months to replace or recharge the device's power source (typically a battery). One-way devices simply broadcasting their status (one-way) such as automated utility meter readers have a better battery life, typically requiring replacement within 10 years. For both device types, scheduled power-source maintenance is costly and disruptive to the entire system that a device is intended to monitor and/or control. Unscheduled maintenance trips are even more costly and disruptive. On a macro level, the relatively high cost associated with the internal battery also reduces the practical, or economically viable, number of devices that can be deployed.

[0005] The ideal solution to the power problem for untethered devices is a device or system that can collect and harness sufficient energy from the external environment. The harnessed energy would then either directly power an untethered device or augment a battery or other storage component. Directly powering an untethered device enables the device to be constructed without the need for a battery. Augmenting a storage component could be along two lines: 1) increasing the overall life of the device or 2) by providing more power to the device to increase the functionality of the device. The other parameters for an ideal solution is that the harnessing device could be used in a wide range of environments including harsh and sealed environments (e.g. nuclear reactors), would be inexpensive to produce, would be safe for humans, and would have a minimal effect on the basic size, weight and other physical characteristics of the untethered device.

SUMMARY

[0006] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises a power harvester (preferably a radio frequency (RF) energy harvester) connected to the core device to power the core device.

[0007] The present invention pertains to an apparatus for an application. The apparatus comprises a core device preferably having an integrated circuit for the application. The apparatus comprises means for receiving energy wirelessly and providing power from the energy to the core device to power the integrated circuit of the core device. The receiving means is connected to the core device.

[0008] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit of the core device with the usable energy.

[0009] This invention pertains to a technique that uses radio frequency (RF) energy as a source of energy to directly power a device or augment a power storage component in a device. The present invention meets the requirements described in the previous "Background of the Invention" section.

[0010] Traditional RF receiving devices have focused on maximizing selectivity of the frequency to isolate and to be coherent without interference from other sources. In contrast, while the present invention operates at a specific frequency or range of frequencies, the device accepts any interference to supplement the output power of the device. Also, the research related to power harvesting that uses RF energy as a source has primarily focused on devices in close proximity of the source (inductive or near-field energy). In most cases, prior research assumed a dedicated or directed source of RF to power the device.

[0011] The invention should not be confused with power transfer by inductive coupling, which requires the device to be relatively close to the power transmission source. The RFID Handbook by the author Klaus Finkenzeller defines the inductive coupling region as distance between the transmitter and receiver of less than 0.16 times lambda where lambda is the wavelength of the RF wave. The invention can be implemented in the near field (sometimes referred to as inductive) region as well as the far-field region. The far-field region is distances greater than 0.16 times lambda.

[0012] It is an object of this invention to provide a method and apparatus to

[0013] 1. remotely energize an untethered device without using direct wiring

[0014] 2. power or augment the life of the power storage component so it matches the life of the device and, ultimately, powers the off-grid device with or without the use of batteries

[0015] 3. allow untethered devices to be virtually maintenance free

[0016] 4. provide augmentation for other energy harvesting technologies (solar, piezoelectric, etc.)

[0017] 5. provide backup power to tethered devices

[0018] It is a further object of this invention to directly power a device or augment a power storage component in a device in conjunction with other power harvesting technologies and storage elements.

[0019] With this method and apparatus a device's power storage components do not require replacement, thus enabling the device to be permanently placed off-grid, where it may be physically impractical, costly, or dangerous (due to a harsh environment) to provide maintenance.

[0020] For devices on-grid (tethered) or with reliable power sources, RF power harvesting can be used as a backup in case the primary power source is lost.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] In the accompanying drawings, the preferred embodiment of the invention and preferred methods of practicing the invention are illustrated in which:

[0022] FIG. **1** is a block diagram of an RF Power Harvesting block used to directly supply power to Core Device Components.

[0023] FIG. **2** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0024] FIG. **3** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0025] FIG. **4** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0026] FIG. **5** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0027] FIG. **6** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0028] FIG. **7** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0029] FIG. **8** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block.

[0030] FIG. **9** is a block diagram of an RF Power Harvesting block in communication with a Power Storage block and used to supply power to Core Device Components.

[0031] FIG. **10** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0032] FIG. **11** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0033] FIG. **12** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0034] FIG. **13** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0035] FIG. **14** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0036] FIG. **15** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0037] FIG. **16** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0038] FIG. **17** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block.

[0039] FIG. **18** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger.

[0040] FIG. **19** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and the RF Power Harvesting block in communication with a Power Storage block.

[0041] FIG. **20** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components.

[0042] FIG. **21** is a block diagram of an RF Power Harvesting block supplying power to a Power Storage Charger and Core Device Components and the RF Power Harvesting block in communication with a Power Storage block.

[0043] FIG. **22** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0044] FIG. **23** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0045] FIG. **24** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0046] FIG. **25** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0047] FIG. **26** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0048] FIG. **27** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0049] FIG. **28** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and the RF Power Harvesting block supplying power to Core Device Components.

[0050] FIG. **29** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit.

[0051] FIG. **30** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and Power Storage block and used to supply power to Core Device Components.

[0052] FIG. **31** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0053] FIG. **32** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power Core Device Components.

[0054] FIG. **33** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or

Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0055] FIG. **34** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block.

[0056] FIG. **35** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components.

[0057] FIG. **36** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0058] FIG. **37** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components.

[0059] FIG. **38** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0060] FIG. **39** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0061] FIG. **40** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to the Power Storage Charger.

[0062] FIG. **41** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0063] FIG. **42** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0064] FIG. **43** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to a Power Storage Charger.

[0065] FIG. **44** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and the RF Power Harvesting block supplying power to Core Device Components and used to supply power to a Power Storage Charger.

[0066] FIG. **45** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to a Power Storage Charger.

[0067] FIG. **46** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0068] FIG. **47** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to a Power Storage Charger.

[0069] FIG. **48** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power Core Device Components and used to supply power to a Power Storage Charger.

[0070] FIG. **49** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0071] FIG. **50** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to a Power Storage Charger.

[0072] FIG. **51** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0073] FIG. **52** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0074] FIG. **53** is a block diagram of an RF Power Harvesting block in communication with a Power Regulation and/or Power Storage Circuit and a Power Storage block and used to supply power to Core Device Components and used to supply power to a Power Storage Charger.

[0075] FIG. **54** is a block diagram of an RF Power Harvesting block using Antenna A to directly supply power to Core Device Components.

[0076] FIG. **55** is a block diagram of an RF Power Harvesting block using Antenna A to supply power to a Power Regulation, Storage and/or Storage Charging block.

[0077] FIG. **56** is a block diagram of an RF Power Harvesting block using Antenna A to supply power to a Power Regulation, Storage and/or Storage Charging block and used to supply power to Core Device Components.

[0078] FIG. **57** is a block diagram of an RF Power Harvesting block used to directly supply power to Core Device Components.

[0079] FIG. **58** is a block diagram of an RF Power Harvesting block used to supply power to a Power Regulation, Storage and/or Storage Charging block.

[0080] FIG. **59** is a block diagram of an RF Power Harvesting block used to supply power to a Power Regulation, Storage and/or Storage Charging block and used to supply power to Core Device Components.

[0081] FIG. **60** is a block diagram of an RF Power Harvesting block used to directly supply power to Core Device Components.

DETAILED DESCRIPTION

[0112] A complete understanding of the invention will be obtained from the following description when taken in connection with the accompanying drawing figures wherein like reference characters identify like parts throughout.

[0113] There is shown an apparatus **10** for an application. The apparatus **10** comprises a core device **22** preferably having an integrated circuit **36** for the application. The apparatus **10** comprises a power harvester **20** connected to the core device **22** to power the core device **22**.

[0114] The apparatus **10** preferably includes an alternative power source **24** connected to the core device **22** to power the core device **22** in conjunction with the power harvester **20**. Preferably, the apparatus **10** includes a power regulator **26** and/or power storage circuit **28** connected to the power harvester **20**. The apparatus **10** preferably includes a power storage charger **30** connected to the power harvester **20**. Preferably, the apparatus **10** includes a power storage connected to the power harvester **20**.

[0115] Preferably, the core device **22** includes a memory **38** connected to the integrated circuit **36** and to the power harvester **20** to power the memory **36**.

[0116] The core device **22** can include a sensor **32**, as shown in FIG. **89**. The sensor **32** can include a proximity sensor, an intrusion sensor, an environmental sensor, a chemical sensor, a biological sensor, a sensor in contact with an automobile, an occupancy sensor, a motion sensor, a position sensor, a metal detector, or a sensor **32** in contact with an aircraft. The sensor **32** can include an alarm connected to the power harvester **20** to power the alarm, a display connected to the power harvester **20** to power the display, a sensor **32** disposed in a building, an industrial automation sensor, a sensor **32** in contact with an elevator, a temperature sensor, a fire sensor, or an accelerometer.

[0117] The sensor **32** can include a level sensor, a gas level sensor, a fluid level sensor, a light level sensor. The sensor **32** can include a flow sensor, a gas flow sensor, a fluid flow sensor, a light flow sensor, or a plasma flow sensor.

[0118] The sensor **32** can include a pressure sensor, a gas pressure sensor, a fluid pressure sensor, a light sensor, an infrared light sensor, an ultraviolet light sensor, an x-ray sensor, a cosmic ray sensor, a visible light sensor, a gamma ray sensor, a stress sensor, a strain sensor, a depth sensor, or an electrical characteristic sensor.

[0119] The sensor **32** includes a voltage sensor, a current sensor, a viscosity sensor, an acoustical sensor, a sound sensor, a listening sensor, a thickness sensor, a density sensor, a surface quality sensor, a volume sensor, a physical sensor, a mass sensor, a weight sensor, a conductivity sensor, a distance sensor, an orientation sensor, or a vibration sensor.

[0120] The sensor **32** can include a radioactivity sensor, a field strength sensor, an electric field sensor or a magnetic field sensor, a smoke detector, a carbon monoxide detector, a radon detector, an air quality sensor, a humidity sensor, a glass breakage sensor, or a break beam detector. The sensor can include a thermal energy sensor, an electromagnetic sensor, a mechanical sensor, an optical sensor, a radiation sensor, a sensor in contact with a vehicle, or a sensor **32** in contact with a water craft.

[0121] The present invention pertains to an apparatus **10** for an application. The apparatus **10** comprises a core device **22** having an integrated circuit **36** for the application. The apparatus **10** comprises means for receiving energy wirelessly and providing power from the energy to the core device **22** to power the integrated circuit **36** of the core device **22**. The receiving means is connected to the core device **22**. Preferably, the core device **22** includes means for sensing.

[0122] The present invention pertains to a method for an application. The method comprises the steps of converting RF energy into usable energy. There is the step of preferably powering an integrated circuit **36** of the core device **22** with the usable energy.

[0123] Preferably, there is the step of regulating the usable energy provided to the core device **22**. There is preferably the step of storing the usable energy. Preferably, there is the step of providing power to the core device **22** from an alternative power source **24** in conjunction with the usable energy.

[0124] Alternatively, the core device **22** can include a computer peripheral **34**, as shown in FIG. **90**. The computer peripheral **34** can include a handheld game, a gaming system, a game controller, a controller, a keyboard, a mouse, a computer terminal, computer storage, or computer equipment.

[0125] The present invention can be implemented in numerous ways. A number of these ways are depicted in FIGS. **1-90**. These figures contain multiple blocks that are configured in multiple ways.

[0126] In the figures, an arrow represents the flow of power unless otherwise stated. Single-headed (one-way) arrows represent that the power is flowing from one block to another. The single-headed arrow may represent multiple wires that provide power from one block to multiple parts in the other block. Two-headed (two-way) arrows represent a single wire that can have power flow in either direction or multiple wires each having power flow in a single direction.

[0127] As an example, a two-headed arrow between an RF power harvesting **20** block and a power regulation **26** and/or power storage circuit **28** block can represent a single wire that allows harvested power to flow into a storage device such as a capacitor. The same block diagram can also represent two wires between the two blocks with the first wire allowing harvested power to flow into a voltage regulator **26**. The second wire can allow the regulated voltage to feedback to the RF power harvesting **20** block to provide power to internal components such as transistors to increase the performance of the RF power harvesting **20** block.

[0128] Each block is described in detail below. Each block represents the functionality described below associated with it. For instance, the RF power harvesting **20** block describes a power harvester **20**, and the power regulation **26** and/or power storage circuit **28** block describes a power regulator **26** and a power storage circuit **28**.

Device's Power System Block

[0129] The device's power system block includes all components/circuitry required to power the device. This block may include an RF power harvesting **20** block, a power regulation **26** and/or power storage circuit **28** block, a power storage block, and/or a power storage charger **30** block (all discussed below).

RF Power Harvesting **20** Block

[0130] The RF power harvesting **20** block is connected to an antenna. The antenna may or may not be used as the communications antenna for the core device **22** components. The RF power harvesting **20** block is used to convert the energy captured by the antenna into usable power, such as direct current (DC) voltage.

[0131] This block may include antenna matching, rectifying circuitry, voltage transforming circuitry, and/or other performance optimizing circuitry. The rectifying circuitry may include a diode(s), a transistor(s), or some other rectifying device or combination. Examples of the rectifying circuitry include, but are not limited to, half-wave, full-wave, and voltage doubling circuits.

[0132] The output of the RF power harvesting **20** block is a DC voltage or current. The RF power harvesting **20** block may accept feedback (or input) from other circuitry or blocks, which may be used to control the harvesting circuitry to improve the performance or vary the output. This feedback may include, but is not limited to, a DC voltage or a clock from the core device **22** components.

[0133] U.S. Pat. No. 6,615,074 (FIGS. **8**, **9**, **12***a*, **12***b*, **13**, **14**), incorporated by reference, herein, shows numerous examples of RF power harvesting circuits that can be used to implement the block and function described.

Power Regulation **26** and/or Power Storage Circuit **28** Block

[0134] It may be necessary to regulate the converted power (i.e., hold the power at a constant level) for specific devices. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications.

[0135] The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or switching regulator **26** to hold the voltage at a constant level.

[0136] Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

[0137] This block may also include, with or without the regulation, a storage device such as a capacitor, a battery, or some other device able to store charge. The output from the power regulation **26** and/or power storage circuit **28** block may be used as feedback to other blocks within the device's power system block or to the alternative power sources **24** block (described below), if they require a regulated supply voltage or stored power.

[0138] U.S. Pat. No. 6,894,467 (FIGS. **1**, **3**), Linear Voltage Regulator, incorporated by reference, herein, is an example of a practical application of implementing the regulation described in the block. U.S. Pat. No. 6,297,618 (FIGS. **1-4**), Power storage device and method of measuring voltage of storage battery, incorporated by reference, herein, is an example of a practical application of implementing the storage described in the block.

Power Storage Charger **30** Block

[0139] The power storage charger **30** block may be needed if a power storage component of the device requires a special charging mechanism, such as pulse charging or trickle charging. This block controls how the captured and converted power is supplied to the power storage component.

[0140] U.S. Pat. No. 6,836,095 (FIGS. **1-3**), Battery Charging Method and Apparatus, incorporated by reference herein, is an example of a practical application of implementing the special charging mechanism described in the block.

Power Storage Block

[0141] If a device has intermittent power requirements, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block, which could include a battery, a capacitor, and/or another type of power storage component. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other power storage elements.

[0142] The output from the power storage block may be used as feedback to other blocks within the device's power system or to the alternative power sources **24** block, if they require a dedicated and predictable supply voltage.

[0143] U.S. Pat. No. 6,297,618 (FIGS. **1-4**), Power Storage Device and Method of Measuring Voltage of Storage Battery, incorporated by reference herein, is an example of a practical application of implementing the storage described in the block. U.S. Pat. No. 6,835,501, Alkaline Rechargeable Battery, incorporated by reference herein, is also an example of a practical application of implementing the storage described in the block.

Core Device **22** Components Block

[0144] The core device **22** components block is the portion of the device that is receiving power from the device's power system. This block may be, but is not limited to, the devices listed in the subsequent pages of this document. It may be advantageous for the core device **22** components block to communicate with any of the blocks that are supplying power to it. This communication can include, but is not limited to, a feedback control signal such as a clock or an ON/OFF command. As an example, the device may want to turn off the alternative power sources **24** block if it is receiving sufficient power from the RF power harvesting **20** block.

Alternative Power Sources **24** Block

[0145] RF energy harvesting also has the ability to be augmented by other types of power harvesting, storage components, or dedicated sources (e.g. power line). The alternative power sources **24** block shows how this type of system could be implemented. The augmenting power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. This block can work independently or have communication with other blocks.

[0146] U.S. Pat. No. 6,784,358, Solar Cell Structure Utilizing an Amorphous Silicon Discrete By-Pass Diode, incorporated by reference herein, is an example of a practical application of implementing an alternative power source **24** described by the block. U.S. Pat. No. 6,858,970, Multi-Frequency Piezoelectric Energy Harvester, incorporated by reference herein, is also an example of a practical application of implementing an alternative power source **24** described by the block.

Power Regulation **26**, Storage **28** and/or Storage Charging **30** Block

[0147] The power regulation **26**, storage **28** and/or storage charging **30** block contains all the combinations of the power regulation **26** and/or power storage circuit **28** block, power storage charger **30** block, and power storage block. This block is used in the later figures to reduce the number of figures needed to show how the blocks can interconnect.

[0148] The disclosed invention is an apparatus and method for an application for retrieving radio frequency (RF) energy by an antenna, converting that energy into direct current (DC) power, regulating that energy using an optimized circuit, storing that energy in an optimized component, and/or supplying the power for a specific device.

Retrieval of RF Energy

[0149] The RF energy is retrieved from the environment by the use of the antenna. The antenna can be shared or standalone with respect to an antenna used for the device's wireless communication. FIGS. **54-56** show a device that has an antenna A for use by the RF power harvester **20** and an antenna B used for wireless one-way or two-way communication. FIGS. **57-59** show a device where the antenna is shared by both a device's communication module (within the core device **22** components) and the RF power harvester **20**. In terms of form factor, the antenna used by the apparatus **10** can be a separate component or integrated directly into the form factor of the device.

[0150] The antenna is able to capture two types of available RF energy. The first type of energy exists as ambient RF energy. This type of RF surrounds us in our day-to-day lives and is usually generated to carry one way or two-way combinations of voice, video and data communications. The sources that the antenna can harvest from include, but are not limited to, medium-frequency AM radio broadcast, very-high-frequency (VHF) FM radio broadcast and television broadcast, ultra-high-frequency (UHF) broadcast, cellular base stations, wireless data access points, super-high-frequency (SHF) frequencies, and the industrial, scientific, and medical (ISM) bands. These sources cover transmission frequencies from 300 kHz to 30 GHz.

[0151] The second type of energy available is directed RF energy. This type of RF energy is directed from a transmitter specifically designed to deliver RF energy for harvesting by the antenna. The transmitter can be configured as a standalone device or integrated into an existing device.

Conversion of the Energy into DC

[0152] The RF energy captured by the antenna must be converted into a useful form of energy for the specific device. This conversion is shown in block form in all FIGS. (**1-90**) as the RF power harvesting **20** block. The most common form of useable energy is DC energy. To perform this conversion, the block includes circuitry to rectify the captured alternating current (AC) energy to create DC energy. The rectification in this block can be done with a diode(s), a transistor(s), or some other rectifying device or combination.

Regulation of the Energy

[0153] It may be necessary to regulate the converted power (hold the power at a constant level) for specific devices. FIGS. **2-7**, **10-17**, and **22-53** show how this regulation can be implemented using a power regulation **26** and/or power storage circuit **28** block. The devices that would need this block require a fairly constant voltage or current. Deviations from the required values may cause the device to not perform within its specifications. The regulation can be implemented in many different ways. The block can be as simple as using a Zener diode, or as complicated as using an integrated circuit such as a linear voltage regulator **26** or a switching regulator **26** to hold the voltage at a constant level. Certain devices have a more tolerable power requirement. For these devices, the regulation stage may be excluded.

Storage of the Energy

[0154] If a device has intermittent power requirements, such as the devices exampled by FIGS. **2-53**, it may be necessary to store the captured power for use at a later time. The power can be stored in the power storage block or the power regulation **26** and/or power storage circuit **28** block. Storage devices can include, but are not limited to, a battery, a capacitor, or another type of power storage component. In certain applications, it may be necessary to include additional circuitry that controls how the power is transferred to the storage device. The power storage charger **30** block is shown in FIGS. **18-53**. This may be needed if the power storage component requires a special charging mechanism such as pulse charging or trickle charging. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. There are devices that will not require storage. These devices can run directly off of the converted power. These devices also may or may not require regulation of the captured power.

Supplying the Power

[0155] The captured DC power, which may or may not be regulated and/or stored, is supplied to the device, which is represented by the core device **22** components block in the figures. This may be a single connection or it may supply multiple parts of the device with power.

[0156] RF energy harvesting also has the ability to be augmented by other types of power harvesting or storage components. Other power harvesting technologies include, but are not limited to, solar, light (visible and non-visible), piezoelectric, vibration, acoustic, thermal, microgenerators, wind, and other environmental elements. Power storage components include, but are not limited to, batteries (rechargeable and non-rechargeable), capacitors, inductors, fuel cells, and other storage elements. FIGS. **60-88** show how the alternative power sources **24** block can be connected to an RF energy harvesting system. These figure show how the RF energy harvesting **20** block and the alternative power sources **24** block can work independently or have communication with each other. The antenna configurations shown in FIGS. **54-59** are still applicable with the addition of an alternative power sources **24** block. These antenna configurations can be applied to FIGS. **60-88**.

[0157] RF energy harvesting also has the ability to provide a backup to devices on-grid (tethered) or with reliable power sources, which can be used in case the primary power source is lost. As an example, it may be mandated by regulations that a sensor has auxiliary power in case the primary supply is lost. It could be possible to use a rechargeable battery that obtains its charge from the primary supply when in operation. However, if the primary supply is lost for a time greater than the life of the rechargeable battery, the specification of uninterrupted power is not met. RF energy could be used to supply power to the described device while the primary supply is not available. The primary supply could include, but is not limited to, an on-grid connection, a generator, a battery, or other reliable power supply.

[0158] RF energy harvesting with or without alternative source augmentation is applicable to provide electric power directly or indirectly to a range of electronic components contained in any specific electrical or electronic device and includes, but is not limited to:

[0159] Passive electronic components, active electronic components;

[0160] Resistors, fixed resistors, variable resistors, thermistors, thyristor, thermocouple;

[0161] Capacitors, Electrolytic Capacitors, Tantalum Capacitors, Ceramic Capacitors, Multilayer Ceramic Capacitors, Polystyrene Film Capacitors, Electric Double Layer Capacitors (Super Capacitors), Polyester Film Capacitors, Polypropylene Capacitors, Mica Capacitors, Metallized Polyester Film Capacitors, Variable Capacitors;

[0162] Diodes, Voltage regulation diodes, light-emitting diodes, organic light-emitting diodes, Variable capacitance diodes, Rectification diodes, Switching diodes, Regulation Diodes, Diode bridges, Schottky barrier diodes, tunnel diodes, PIN diodes, Zener diodes, Avalanche diodes, TVSs;

[0163] Integrated circuits, microcontroller unit (MCU), microprocessor unit (MPU), logic circuits, memory, printed circuits, circuit boards, printed wiring boards;

[0164] Transistors, MOSFETs, FETs, BJTs, JFETs, IGBTs, Relays, Antennas, semiconductors, conductors, inductors, relays, diacs, triacs, SCRs, MOVs;

[0165] Fuses, circuit breakers;

[0166] Batteries, Non-rechargeable batteries, rechargeable batteries, coin cell batteries, button cell batteries, alkaline batteries, lithium batteries, lithium ion batteries, lithium polymer batteries, NIMH batteries, NICAD batteries, Lead acid batteries, Zinc air batteries, Manganese Lithium batteries, Niobium Titanium Lithium batteries, Vanadium Pentoxide Lithium batteries, Carbon

Zinc batteries, Zinc Chloride batteries, Lithium Thionyl Chloride batteries, Manganese Dioxide batteries, Lithium Poly-Carbonmonofluoride batteries, Lithium Manganese Dioxide batteries, Lithium Chloride batteries, Lead Acid Calcium batteries, Lead Acid Tin batteries, Oxy Nickel batteries, Silver Oxide batteries, Magnesium batteries;

[0167] Inductors, Coils, High Frequency Coils, Toroidal Coils, Transformers, switches, chokes;

[0168] Motors, DC motors, stepper motor, AC motors, Fans;

[0169] Crystals, Oscillators, Clocks, Timers; and

[0170] Displays, LCDs, LED displays.

[0171] RF energy harvesting with or without alternative source augmentation is applicable across a range of markets and specific devices and includes but is not limited to:

[0172] Consumer electronics:

[0173] Electronic equipment, wired devices, battery powered devices, wireless communication devices, cell phones, telephones, phones, cordless phones, portable phones, Bluetooth devices, Bluetooth headsets, hands-free headsets, headsets, headphones, Wireless headsets, radios, AM/FM radios, shortwave radios, weather radios, Two-way radios, portable radio, lights, lanterns, portable lights, flashlights, nightlights, spotlights, search lights, calculators, graphing calculators, desk calculators, clocks, alarm clocks, wall clocks, desk clocks, travel clocks, watches, wristwatches, pocket watches, stop watches, timers, voice recorders, Dictaphones, laser pointers, power tools, cordless power tools, electronic razors, electric razors, handheld games, gaming systems, game controllers, wireless game controllers, remote controls, battery chargers, computers, portable computers, keyless entry, toys, toy guns, toy laser guns, games, microphones, musical instruments, musical effects processors, musical instrument tuners, metronomes, electronic chord charts, door openers, garage door openers, PDA, Cameras, Video recorders, Multimeter, electronic test equipment, hand-held electronics, portable electronics, wireless pens, sound generators, noise generators, language translators, electric toothbrushes, portable televisions, pagers, transceivers, toy vehicles, remote control vehicles, toy planes, remote control planes, pet containment systems, invisible fence pet sensors, memory backup, base station battery backups, appliance battery backups, uninterrupted power supplies, GPS devices, memory retention power supplies, metal detectors, stud finders, metal stud finders, stun guns, tazers, wearable devices, baby monitors, intercoms, doorbells, wireless doorbells, electronic office supplies, electronic staplers, radar jammers, radar detectors, digital scales, microfilm cassettes, video head testers, compasses, noise canceling headphones, air samplers, depth finders, barometers, weather measurement instruments, data transfer devices, automatic distress signaling unit, Wireless audio speakers, Satellite radios, Police scanners, Car navigation systems (GPS devices), Decorative lights, Christmas lights, garden lights, lawn lights, ornamental lights, porch lights;

[0174] Multi-media players: MP3, DVD, analog music players, CD players, tape players, digital music players, digital video players, minidisc; and

[0175] Computer: keyboards, mice, peripherals, computer equipment, electronic computers, computer storage, computer terminals;

[0176] Building/Industrial Automation:

[0177] Sensors: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity, glass breakage, break beam detector;

[0178] Controls: Position, elevator, temperature, fire, accelerometers, level, gas level, fluid level, light level, flow, gas flow, fluid flow, light flow, plasma flow, pressure, gas pressure, fluid pressure, motion, light, infrared light, ultraviolet light, X-rays, cosmic rays, visible light, gamma rays, chemical, stress, strain, depth, electrical characteristics, voltage, current, viscosity, acoustical, sound, listening, thickness, density, surface quality, volume, physical, mass, weight, force, conductivity, distance, orientation, vibration, radioactivity, field strength, electric field strength, magnetic field strength, occupancy, smoke detector, carbon monoxide detector, radon detector, air quality, humidity; and

[0179] Devices: Thermostats, light switches, door locks, smart-card door locks, lighting, emergency lighting, motion lighting, safety lighting, highway lighting, construction lighting, sign lighting, roadway sign lighting, construction sign lighting, automatic flushing units, automatic soap dispenser, automatic paper towel dispenser, automatic faucets, automatic door sensors, identification reader, fingerprint reader, credit card readers, card readers, valve actuators, gauges, analog gauges, digital gauges, fire extinguishers, wireless switches, remotely operated inspection equipment, gas/oil pipeline monitoring systems, robotic pipeline inspection gauges, "auto-reclosers" for electric power lines, sonar buoys, telemetry systems, electronic record tracking systems, robbery tracking devices, interrogators, programmers, emergency exit alarms, alarms, flood alarms, gas alarms, electronic entry systems, security keypads, silo transducers, data recorders, signal tracers, antistatic strap testers, radiosonde weather balloons, utilities load controllers, profilometers, noise cancellation equipment, infrared beacons;

[0180] Military/Government:

[0181] Tracking tags: Weapons, vehicle, soldier, gear/assets, staff, general population, security access badges;

[0182] Sensors: Proximity, intrusion, environmental, chemical/biological; and

[0183] Equipment: Battery charger, surveillance, card readers, identification reader, fingerprint reader, retinal scanners, satellites, rockets, space vehicles, search and rescue transponders (SARTs), emergency position-indicating rescue beacons (EPIRBs), emergency locator transmitters (ELTs), military radios, electronic toll collection systems, postal tracking systems, communica-

tions, thermal imaging, night vision, training targets, field medical equipment, house arrest monitors, laser tags, electronic parking meters, multiple integrated laser engagement system, munitions and mines, ship sensors;

[0184] Utility:

[0185] Gas consumption meters, water consumption meters, and electric consumption meters;

[0186] Logistics & Supply Chain Management:

[0187] Radio-frequency identification devices (RFID), RFID readers;

[0188] Tracking: Asset tags, cargo container location beacons, transponders, transceivers; and

[0189] Devices: Smart price tags, smart shelving, hand-held barcode scanner, barcode scanners, credit card readers, card readers, retail signage, hotel door locks;

[0190] Homeland Security:

[0191] Sensors: Occupancy, proximity, environmental, chemical/biological, motion, position; and

[0192] Metal detector wand;

[0193] Medical:

[0194] Implantable: cochlear implants, neural stimulators, pace makers, medication administration, defibrillator;

[0195] Body function monitors: pressure, temperature, respiration, blood oxygenation, insulin, hearing aid, pulse, EKG, heart, Holter;

[0196] Tracking tags: Patient, baby identification, assets, supplies, staff, medication, instruments;

[0197] Devices: Home healthcare equipment, ambulatory infusion pumps, blood analyzers, biofeedback systems, bone growth stimulators, thermometers, digital thermometers, stimulators, galvanic stimulators, muscle stimulators, pediatric scales; and

[0198] Agriculture—livestock tracking and asset tracking:

[0199] Tracking: livestock, asset, wildlife tracking devices; and

[0200] Equipment: cattle prods;

[0201] Automotive:

[0202] Automotive antennas, Automotive Audio Systems, Automotive Lighting, Automotive Video Systems, Computers, Processors, Controls, Switches, Electric Motors, Actuators, Ignition Systems, Starter Systems, Injection Systems, Powertrain Electronics, Radar Detectors, Proximity Detectors, Safety Systems, Security Systems, Sensors, Regulators, Distributors, Vehicle Control, Wiper Systems, Washer Systems, Radio, Video Systems, Entertainment Systems, Navigation Systems, GPS systems, Power Mirror Systems, Emission control systems;

[0203] Appliances:

[0204] Monitoring systems and control systems for major and small appliances including washing machines, dryers, refrigerators, freezers, coolers, air conditioners, humidifiers, dehumidifiers, air purifiers, air filters, fans, furnaces, water heaters, boilers, space heaters, sowing machines, ice makers, microwave ovens, convection ovens, ovens, toaster ovens, ranges, range hoods, cooktops, stoves, stovetops, crock pots, hot plates, dishwashers, garbage disposals, can openers, vacuum cleaners, blenders, mixers, food processors, irons, coffee makers, toasters, grills, hair dryers, electric tooth brushes, electric razors, electric drills, electric screwdrivers, chainsaws, lawnmowers, push mowers, riding mowers, trimmers, brush cutters, pruners, edgers, vending machines;

[0205] Ventilation, Heating, Air-Conditioning, and Commercial Refrigeration Equipment:

[0206] Monitoring systems, control systems;

[0207] Engine, Turbine, and Power Transmission Equipment;

[0208] Monitoring systems, control systems;

[0209] Other General Purpose Machinery Manufacturing:

[0210] Monitoring systems, control systems;

[0211] Telecommunications:

[0212] Monitoring systems, control systems;

[0213] Portable;

[0214] Aircraft:

[0215] Monitoring systems, control systems, actuator systems, sensors.

[0216] It should be noted that devices within a specific category may be applicable across multiple areas even if they are not specifically listed. (e.g., temperature sensors apply to Industrial and Building Automation and Appliances).

[0217] To retrofit or redesign the devices listed, it is possible to implement the described systems in numerous ways. It may be advantageous to leave the device design as-is including the existing power supply. As an example, a device may use non-rechargeable batteries to operate. The device will most likely have a protection circuit to prevent damage if the batteries are installed incorrectly. The protection mechanism is commonly a diode inline with the positive terminal of the battery. In this case, the RF power harvester **20** with or without the alternative power source **24** could be inserted, with an antenna, into the device. The power generated by the RF power harvester **20** (and the alternative power source **24**, if applicable) could be connected to the device after the protection mechanism described to avoid potential charging of a non-rechargeable battery.

[0218] Another way to configure the device's power system is to replace the non-rechargeable batteries with rechargeable batteries. In this instance, the output from the RF power harvester **20** (and alternative power source **24**) could be connected to either side of the protections device. If the connection is before the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will recharge the battery and supply power to the device. If the connection is after the protection mechanism, the RF power harvester **20** (and the alternative power source **24**, if applicable) will supply power to the device and the battery will supply any extra power needed that could not be supplied by the RF power harvester **20** (and the alternative power source **24**, if applicable). It should be noted that the protection device in this case is not needed for proper operation. Its only function would be to protect the batteries from being installed incorrectly. An antenna could be contained inside or placed on the outside of the device.

[0219] Another configuration of the device's power system is to remove the existing batteries and install the RF power harvester **20** (and the alternative power source **24**) in the enclosure provided for the batteries. An antenna could be contained inside or placed on the outside of the device.

[0220] Yet another method of configuring the device's power system would be to reduce the number of batteries and replace them with the RF power harvester **20** (and the alternative power source **24**). In this case, the output from the system would be connected to the batteries in series or par-

allel depending on the original battery configuration. An antenna could be contained inside or placed on the outside of the device.

[0221] An additional option, would be to completely redesign the product and integrate the required circuitry and storage components into the device. This method is probably the most advantageous because it can fully take advantage of the benefits offered by the RF power harvester **20** (and the alternative power source **24**). An antenna could be contained inside or placed on the outside of the device.

[0222] If the RF power harvester **20** (and the alternative power source **24**) is used as a backup to the primary power supply, a switch could be implemented into the system in order to switch the RF power harvester **20** (and the alternative power source **24**) on when the primary source is lost. In this case, an antenna could be contained inside or placed on the outside of the device.

[0223] To show the flexibility of RF energy harvesting, several products were retrofitted to include an RF power harvester **20** (energy harvesting circuitry). These products include a wireless keyboard, a wall clock, and a desk calculator.

[0224] The wireless keyboard is an example of recharging and augmenting a battery to supply power to a device. This system is shown in FIG. **13**. The output from the regulation circuitry recharges the battery and supplies power to the keyboard. The battery is also used to supply power to the keyboard. The keyboard also includes a separate antenna for receiving power and for data communications. The antenna configuration can be seen in FIG. **55**.

[0225] The wall clock is an example of a direct powering system. The wall clock was retrofitted to include an RF power harvester **20** and the internal AA battery was removed. This system is shown in FIG. **2**. The wall clock did not need regulation, but did require a capacitor for storage to supply the pulse of power to move the second hand.

[0226] The calculator is an example of using RF energy harvesting with another energy harvesting technology. The calculator had an internal 1.5V coin cell battery and a small solar panel. The internal battery was removed, however, the solar panel was left intact. This system is shown in FIG. **60**. In this system, the calculator can receive power from both the solar panel and the RF power harvester **20** to eliminate the need for a battery.

[0227] As an additional example, an RF power harvester **20** (energy harvesting circuit) similar to the ones shown in U.S. Pat. No. 6,615,074 (FIGS. **8**, **9**, **12***a*, **12***b*, **13**, **14**), was connected in series with a 0.5V solar cell. Individually, the solar cell was able to provide 0.480V to a 10 kilo-ohm resistor, which was being used to simulate the core device **22** components. This corresponds to 23 microwatts. The RF power harvesting circuit by itself was able to provide 2.093V across the 10 kilo-ohm resistor when being supplied by 1 milliwatt of RF power. This corresponds to 438 microwatts. The two circuit outputs were then combined in series by connecting the output from the RF energy harvesting circuit to the ground of the solar cell. The output of the solar cell was then connected to the resistor. The other end of the resistor was connected to the ground of the RF energy harvesting circuit. The voltage across the resistor with the circuits connected as shown in FIG. **63** was 2.445V. This corresponds to 598 microwatts.

[0228] As can be seen, the combination of the two technologies produces a result higher than the addition of the individual powers. From this, it can be determined that the two technologies can cooperate in a way that produces favorable results.

[0229] In the example given, the solar cell produces current to supply the load and helps to bias the RF rectifying diodes, which allows the RF energy harvesting circuit to operate a higher efficiency. The solar cell also changes the impedance seen by the RF energy harvesting circuit, which produces a beneficial result. To be more specific, when examining the power output of the individual circuit (solar and RF power harvesting), the sum of the power captured by the individual circuits was 23 μW+438 μW=461 μW. However, when the two circuits are combined and are allowed to work in conjunction with one another, the output power becomes 598 μW. This result shows that combining the two power-harvesting technologies produces a 30 percent increase in the output power for this example. This same technique can be applied to multiple energy harvesting technologies to produce even greater output power. The equations for this example are shown below.

[0230] Individual Circuits

$$P_I=P_1+P_2+\ldots+P_N$$

[0231] Combined Circuits

$$P_C>P_I=P_1+P_2+\ldots+P_N$$

[0232] where P_I is the sum of the individual output powers

[0233] P_C is the output of the combined circuit

[0234] P_1 is the output power from the first power harvesting technology

[0235] P_2 is the output power from the second power harvesting technology

[0236] P_N is the output power from the N^{th} power harvesting technology

[0237] N is the number of power harvesting technologies or circuits.

[0238] As can be seen by the previous examples, RF energy harvesting can be used alone or in conjunction with alternative power sources to power a wide range of devices. The addition of RF energy harvesting technology to the device allows for increased battery life, increased functionality, or the removal of the primary battery.

[0239] Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

What is claimed is:

1. An apparatus, comprising:

a first antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a second antenna different from and electrically isolated from the first antenna, the second antenna configured to wirelessly communicate with the source;

a power harvester electrically coupled to the first antenna and configured to convert the energy received at the first antenna to a DC voltage;

a radio-frequency identification (RFID) device electrically coupled to the power harvester and to the second antenna, the RFID device configured to wirelessly communicate with the source via the second antenna;

an integrated circuit configured to operate based on the DC voltage; and a sensor electrically coupled to the integrated circuit, the sensor configured to operate based on the DC voltage and to detect at least one of an environmental condition associated with a location of the apparatus or a physical condition associated with an item coupled to the apparatus.

2. The apparatus of claim **1**, further comprising:

a regulator coupled to the power harvester and configured to regulate the DC voltage to produce a regulated DC voltage, the sensor configured to operate based on the regulated DC voltage received from the regulator.

3. The apparatus of claim **1**, wherein the integrated circuit is configured to perform an application associated with the at least one of the environmental condition or the physical condition detected by the sensor.

4. The apparatus of claim **1**, further comprising:

an electronic display configured to operate based on the DC voltage.

5. The apparatus of claim **1**, wherein the sensor includes at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, an orientation sensor, or a position sensor.

6. The apparatus of claim **1**, wherein the RFID device does not operate based on a battery, and the sensor does not operate based on a battery.

7. The apparatus of claim **1**, wherein the apparatus is a RFID tag.

8. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage;

a radio-frequency identification (RFID) device electrically coupled to the antenna and configured to wirelessly communicate with the source via the antenna, the RFID device operatively coupled to the power harvester and including an integrated circuit configured to operate based on the DC voltage; and

a sensor electrically coupled to the RFID device and the power harvester, the sensor configured to operate based on the DC voltage and to detect at least one of an environmental condition associated with a location of the apparatus or a physical condition associated with an item coupled to the apparatus,

the integrated circuit configured to perform an application associated with the at least one of the environmental condition or the physical condition detected by the sensor.

9. The apparatus of claim **8**, wherein the power harvester is configured to wirelessly communicate with the source via the antenna.

10. The apparatus of claim **8**, wherein the sensor is electrically coupled to the antenna and is configured to wirelessly communicate with the source via the antenna.

11. The apparatus of claim **8**, further comprising:

a regulator coupled to the power harvester and configured to regulate the DC voltage to produce a regulated DC voltage, the integrated circuit configured to operate based on the regulated DC voltage received from the regulator.

12. The apparatus of claim **8**, further comprising:

an electronic display configured to operate based on the DC voltage.

13. The apparatus of claim **8**, wherein the sensor includes at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, or a position sensor.

14. The apparatus of claim **8**, wherein the RFID device does not operate based on a battery, and the sensor does not operate based on a battery.

15. An apparatus, comprising:

an antenna configured to wirelessly receive energy from a source, the source being remote from the apparatus;

a power harvester electrically coupled to the antenna and configured to convert the energy received at the antenna to a DC voltage to produce a power associated with the DC voltage;

a regulator coupled to the power harvester and configured to regulate the power associated with the DC voltage to produce a regulated power;

a radio-frequency identification (RFID) device electrically coupled to the antenna and configured to wirelessly communicate with the source via the antenna, the RFID device electrically coupled to the power harvester and the regulator, the RFID device including an integrated circuit configured to operate based on at least one of the power received from the power harvester or the regulated power received from the regulator; and

an electronic display electrically coupled to the RFID device and configured to operate, at least in part, based on the regulated power received from the regulator.

16. The apparatus of claim **15**, wherein the electronic display is electrically coupled to the regulator, the electronic display is configured to operate based on the regulated power received from the regulator and the power received from the power harvester.

17. The apparatus of claim **15**, wherein the electronic display is one of a liquid-crystal display (LCD) or a light-emitting diode (LED) display.

18. The apparatus of claim **15**, further comprising:

a sensor configured to operate, at least in part, based on the regulated power received from the regulator, the sensor including at least one of a temperature sensor, a motion sensor, a vibration sensor, a humidity sensor, or a position sensor.

19. The apparatus of claim **15**, wherein the power harvester is configured to wirelessly communicate with the source via the antenna.

20. The apparatus of claim **15**, wherein the RFID device does not operate based on a battery, and the electronic display does not operate based on a battery.

(57) **ABSTRACT**

An electromagnetic generator comprising an antenna that receives radiofrequency energy. The antenna is connected to a rectifier circuit, which is used to charge a first battery using the radiofrequency energy received by the antenna. The first battery supplies power to a control unit, which powers at least one electromagnet to generate a magnetic field. A flywheel having at least one magnet is configured to rotate when the magnetic field is generated. An alternator, connected to the flywheel, charges a second battery based on the rotation of the flywheel. The second battery is then used to supply power to an external device.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of and priority from U.S. Provisional Application No. 62/018,826, filed Jun. 30, 2014, which is herein incorporated by reference in its entirety and for all purposes.

FIELD

[0002] The disclosure relates generally to electromagnetic generators, in particular, electromagnetic generators that utilize radiofrequency signals as an energy input.

BACKGROUND

[0003] Consumers rely on electricity to power various devices and appliances used on a daily basis. For example, electricity is used to charge cell phones, power televisions, heat water, propel cars, cook food, and the like. Electricity is a critical component to everyday life. Consumers typically receive electricity in one of two ways: (1) from a utility company or (2) from an electric generator.

[0004] Often, utility companies rely on large-scale electric generators to create electricity in a similar manner to smaller-scale electric generators used by individuals. Electric generators are devices that convert one form of energy (e.g., mechanical energy) into electrical energy (i.e., electricity), which can be used to power external devices or can be stored in storage devices, such as batteries and capacitors, for later use. For example, some electric generators use mechanical energy input to turn or rotate permanent magnets. The rotating permanent magnets create changing magnetic fields, which react with conductors to drive an electric current. Accordingly, at least a portion of the input mechanical energy is converted into usable electric energy (i.e., electricity). The input mechanical energy may be provided manually (e.g., via a hand crank), provided from the output of an internal combustion engine, provided from a steam driven turbine (e.g., as done in a nuclear or fossil fuel power plant), or the like.

[0005] Large amounts of input mechanical energy are typically required to generate a meaningful amount of electricity. This often requires paying a utility company for a portion of the electricity generated by the utility company or the burning of fossil fuels in an internal combustion engine driven personal generator. Electricity generated by utility companies can be expensive. Additionally, the burning of fossil fuels can be expensive and produces potentially harmful byproducts, such as carbon dioxide, carbon monoxide, sulfur, and the like. Accordingly, improved electricity sources are desired.

SUMMARY

[0006] One embodiment of the present invention relates to an electromagnetic generator comprising an antenna configured to receive radiofrequency energy and a first circuit connected to the antenna and configured to charge a first battery using the radiofrequency energy received by the antenna. A control unit is configured to receive power from the first battery and is further configured to power at least one electromagnet to generate a magnetic field. A rotatable body having at least one magnet is configured to rotate when the magnetic field is generated. A second circuit is connected to the rotatable body and configured to supply power to an external device.

[0007] Another embodiment relates to a method for supplying power using radiofrequency energy. The method includes receiving radio waves through an antenna and converting energy from the radio waves to a first current. The first current is used charge a first battery. At least one electromagnet is powered to produce a magnetic field using energy supplied from the first battery. The method further includes rotating a rotatable body due to the magnetic field produced by the at least one electromagnet and convertin energy produced by the rotation of the rotatable body to a second current. The second current is used to power an external device.

[0008] A further embodiment relates to an electromagnetic generator. The generator includes an antenna configured to receive radiofrequency energy. The generator further includes a rectifier circuit connected to the antenna and configured convert the radiofrequency energy to direct current energy used to charge a first battery. The generator includes a control unit configured to receive power from the first battery and further configured to power at least one electromagnet to generate a magnetic field. The generator further includes a flywheel having at least one magnet and configured to rotate when the magnetic field is generated. The generator includes an alternator mechanically connected to the flywheel and configured to charge a second battery based on the rotation of the flywheel. The second battery is configured to supply power to an external device.

BRIEF DESCRIPTION OF THE FIGURES

[0009] Features, aspects, and advantages of the present invention will become apparent from the following description and the accompanying exemplary embodiments shown in the drawings, which are briefly described below.

[0010] FIG. **1** shows a schematic diagram of an exemplary embodiment of an electromagnetic generator of the present invention.

[0011] FIG. **2** shows a flow chart illustrating a process in which radiofrequency energy is utilized in order to charge a battery to power devices.

[0012] FIG. **3** shows a perspective front view of the electromagnetic generator.

[0013] FIG. **4** shows a perspective back view of the electromagnetic generator.

[0014] FIGS. **5**A-**5**D shows a perspective views of additional embodiments of the electromagnetic generator.

DETAILED DESCRIPTION

[0015] Referring to the figures generally, systems and methods for generating usable quantities of electricity from radio waves via an electromagnetic electricity generator are described. Radio waves are electromagnetic waves that are emitted and received by many different types of devices. Each radio wave contains electromagnetic energy that can be converted into usable electricity through the described electromagnetic electricity generator. The electromagnetic electricity generator utilizes an antenna to receive the radio wave and a rectifier circuit to convert the electromagnetic electricity generator into an electric current. The electric current is used to drive a magnetic flywheel, which generates mechanical energy. The mechanical energy is then converted into electricity, which can be used to charge batteries and/or power devices. The radio waves received by the antenna can be generated from a remote power company or may be scavenged from the ambient environment (e.g., from television broadcasts, radio broadcasts, cellular phone base stations, wireless networking devices, etc.).

[0016] FIG. **1** schematically shows an electromagnetic generator **100** according to an exemplary embodiment. The electromagnetic generator **100** includes an antenna **30** connected to a rectifier circuit **40**. The antenna **30** is configured to receive radio waves **12** from the ambient environment. In some arrangements, the received radio waves have a frequency of approximately 945 MHz. The radio waves **12** generate an alternating current (AC) in the antenna **30**. The radio waves **12** may originate from a dedicated radio wave generation plant (e.g., a utility company) or may be scavenged from the ambient environment (e.g., from television broadcast transmitters, radio broadcast transmitters, cellular phone base stations, wireless networking devices, etc.).

[0017] The generated AC power is then provided from the antenna **30** to the rectifier circuit **40**, which converts the AC power into direct current (DC). This DC power is used to charge a first battery **10**. The first battery **10** is a rechargeable battery. Accordingly, the first battery **10** may be any of a nickel cadmium (NiCd) battery, a nickel metal hydride (NiMH) battery, a lithium ion (LiIon) battery, a sealed lead acid (SLA) battery, or the like. The first battery **10** may include a plurality of individual battery cells. In some arrangements, the first battery **10** includes a charging controller that controls the input of DC power into the first battery **10** to prevent damage to the first battery **10** that may result from overcharging and/or overheating. Because the generator **100** continuously receives radio waves **12** through the antenna **30** and continuously converts the electromagnetic energy of the received radio waves **12** into DC power, the first battery **10** can be continuously charged over time (e.g., trickle charged). The first battery **10** is not limited to a single battery. Alternatively, the first battery **10** may comprise a plurality of batteries. In such arrangements, once one battery of the plurality of batteries is sufficiently charged, other batteries may be charged by the received DC power from the rectifier circuit **40**. This allows for additional storage of electric energy from the radio waves **12**.

[0018] Once the first battery **10** is sufficiently charged, the battery **10** is then used to supply electric power to a control unit **50**. The control unit **50** controls a plurality of electromagnets **55**. Although three electromagnets **55** are shown in FIG. **1**, it should be understood that any number of electromagnets **55** may be utilized by the generator **100**. The control unit **50** includes a power input that receives electric power from the first battery **10**. The control unit **50** includes a processor and memory. The memory stores programming modules that, when executed by the processor, control the operation of the control unit **50** as described in further detail below. The electromagnets **55** are mounted adjacent to a flywheel **60** that has a plurality of permanent magnets **65** affixed thereon. The permanent magnets **65** are positioned about a circumference of the flywheel. The electromagnets **55** are aligned such that the electromagnets **55** project a magnetic field over at least a portion of the flywheel **60** when the electromagnets are powered. In arrangements where a plurality of electromagnetics **55** are utilized by the generator **100**, each of the electromagnets can have a different position with respect to the flywheel **60**. For example, the electromagnets **55** may be positioned around the circumference of the flywheel **60**. Moreover, each of the electromagnets **55** may be further configured to produce different magnetic field strengths with respect to each one another. The flywheel **60** is a cylinder that has a diameter that is significantly larger than its axial length. In some arrangements, the diameter of the flywheel **60** is at least ten times the axial length of the flywheel **60**.

[0019] The flywheel **60** is rotationally coupled to an axle **67**. The axle **67** extends along a central axis of the flywheel **60**. Accordingly, when the flywheel **60** rotates, the axle **67** rotates with the same rotational velocity as the flywheel **60**. The axle **67** is connected to an alternator **70**. When the flywheel **60** rotates, the axle **67** rotates and provides rotational mechanical energy into the alternator **70**. The alternator **70** is an electromechanical device that converts rotational mechanical energy into electricity.

[0020] During operation, the control unit **50** selectively and independently powers each of the electromagnets **55** to generate magnetic fields. The magnetic fields interact with the permanent magnets **65** positioned on the flywheel **60**, which causes the flywheel **60** to spin. In some operating conditions, the control unit **50** will cause the magnetic field generated by a given electromagnet to be of the same polarity as the permanent magnets **65** to repel the permanent magnets **65**. In other operating conditions, the control unit **50** will cause the magnetic field generated by a given electromagnet to be of the opposite polarity as the permanent magnets **65** to attract the permanent magnets **65**. The control unit **50** determines when to power each of the electromagnets **55**, the amount of power to provide to each electromagnet **55** when powered on, the polarity of the magnetic field to be generated, the strength of the magnetic field to be generated, and when to turn off each electromagnet **55** based on at least in part on feedback from a position and speed sensor **68**. The position and speed sensor **68** measures the position and rotational speed of either the flywheel **60** or the axle **67**. By selectively and independently powering each of the electromagnets **55**, the control unit **50** can accelerate the flywheel **60** to a high rotational speed (e.g., above 1000 RPM) and maintain the high rotational speed of the flywheel **60**. The flywheel **60** may be mounted to a low friction bearing such that little energy input is needed to maintain the rotational speed of the flywheel **60**.

[0021] The spinning of the flywheel **60** produces rotational mechanical energy. The rotational mechanical energy is transferred from the flywheel **60** to the alternator **70** via the axle **67**. The alternator **70** converts the mechanical energy into DC power. The DC power output by the alternator **70** is then used to charge a second battery **20**. The second battery **20** is a rechargeable battery. Accordingly, the second battery **20** may be any of a NiCd battery, a NiMH battery, a LiIon battery, a SLA battery, or the like. The second battery **20** may include a plurality of individual battery cells. In some arrangements, the second battery **20** includes a charging controller that controls the input of DC power into the second battery **20** to prevent damage to the second battery **20** that may result from overcharging and/or overheating. The charging controller may provide feedback to the control unit **50** to indicate a charge of the second battery **20**. For example, the charging controller may provide a voltage of the second battery **20** to the control unit **50**. Based on the feedback provided to the control unit **50**, can stop powering the flywheel **60** or accelerate the flywheel **60**. The second battery **20** stores the power until it is needed. As described above with the first battery **10**, the second battery **20** may also comprise a plurality of batteries. These batteries may also be continuously and/or alternately charged and discharged to store and provide power, allowing for an increase in capacity of the generator **100**.

[0022] The power stored by the second battery **20** is then sent to a power inverter **80**, which converts the DC power supplied by the second battery into AC power. The AC power is output from the generator. In some arrangements, the AC power is supplied to a power outlet **90** to supply power to external devices when needed. In other arrangements, the AC power is provided to a power system (e.g., for a building) or to a power grid (e.g., a power grid that supplies a plurality of buildings and devices). In an alternative arrangement, the power inverter **80** is bypassed and DC power is output from the generator **100** (e.g., to power a device via a USB port).

[0023] FIG. **2** illustrates a flow chart of a method **200** of converting radiofrequency energy into electricity according to an exemplary embodiment. Method **200** is performed by the generator **100** as described above with respect to FIG. **1**. In step S**1**, radio waves **12** are received by the antenna **30** and converted to DC power by the rectifier circuit **40**. The DC power is then used to charge the first battery **10** in step S**2**. At step S**3**, the energy stored on the first battery **10** is used to power the control unit **50** and the electromagnets **55**. As described above, the control unit **50** selectively and independently activates and deactivates each electromagnet to generate magnetic fields. The magnetic fields interact with the permanent magnets **65** mounted on the flywheel **60**, which cause the flywheel **60** to rotate at step S**4**. At step S**5**, the rotational mechanical energy of the flywheel **60** is transferred to the axle **67**, and is provided to the alternator **70**, which converts the received mechanical energy into DC power. The DC power is then output to the second battery **20** at step S**6**. The second battery **20** stores the electric energy until needed. When power is needed, it is first converted from DC to AC by the inverter **80** at step S**7**. The AC power is then outputted from the generator **100** at step S**8**. In some arrangements, the AC power is supplied to a power outlet **90** to supply power to external devices when needed. In other arrangements, the AC power is provided to a power system (e.g., for a building) or to a power grid (e.g., a power grid that supplies a plurality of buildings and devices). In an alternative arrangement, step s**7** is bypassed (e.g., the power inverter **80** is bypassed) and DC power is output from the generator **100** (e.g., to power a device via a USB port).

[0024] FIGS. **3** and **4** illustrate perspective front and back views of one embodiment of the electromagnetic generator **100**. The components described above are preferably housed in a case **110** of the generator **100**. As shown in FIGS. **3** and **4**, the generator **100** may include a control panel **120**. The control panel **120** may comprise indicator lights that may indicate to the user the current state of the generator **100** and/or the storage levels of the batteries. The control panel **120** may also indicate to the user other measurements of the system, such as current input or output levels. As shown in FIG. **3**, the generator **100** may also include a power switch **95** to send energy stored in the second battery **20** to the power outlet **90** when required. As shown in FIG. **4**, the generator **100** may further include a cooling system **150**, such as a fan, to prevent overheating of the system. FIGS. **5**A-**5**D illustrate perspective views of an additional embodiment of the electromagnetic generator **100**, with an alternative case and component design.

[0025] The above-described generator **100** may include additional features. For example, the generator **100** may include an integrated cooling system that cools the various components (e.g., the first battery **10**, the second battery **20**, the control unit **50**, etc.) to prevent overheating. The cooling system may be a liquid cooling system or an air cooling system. The generator **100** may include a passive voltage control system and an electrical and a fuse system to prevent any overload problem. In some arrangements, a gearbox is coupled between the rotating axle **67** and the alternator **70** to modify the torque and rotational speed input into the alternator **70**.

[0026] In some arrangements, the above-described generator **100** is distributed by a power delivery company. In such arrangements, the power delivery company may distribute generators to its subscribers. The power delivery company generates wireless signals (e.g., from a transmitter tower). Each generator may have an identifier associated with each subscriber. The identifier can be communicated wirelessly (e.g., through radio-frequency identification, Bluetooth, WiFi, etc.). Alternatively, the identifier may be associated with the entry of a specific user ID into the control panel **120** (e.g., user ID and password, user PIN, etc.). Each generator also includes a data transceiver (e.g., a cellular data transceiver) that provides real-time feedback to the power delivery company relating to an amount of electricity consumed by the associated subscriber. The power delivery company can then accurately bill each of its subscribers for actual electricity used.

[0027] The above-described generator **100** may be adapted to power specific devices. For example, the generator **100** may be integrated into and provide operational power to tools, such as powered gardening equipment (e.g., lawn mowers, weed whackers, electric tree trimmers, etc.), tools (e.g., air compressors, power washers, saws, drills, etc.), hospital equipment to provide off-grid power backup, vehicles or other propulsion systems (e.g., electric motor boats, electric aircraft, electric automobiles, electric motorbikes, etc.), appliances and HVAC equipment (e.g., refrigeration systems, heating systems, clothes washers, clothes dryers, etc.), commercial construction equipment, and the like. The generator **100** may be used as a replacement for traditional fossil fuel based electricity generators, such as diesel or gasoline generators. Furthermore, the generator **100** is not limited in its use of radiofrequency signals from transmission towers. The generator **100** may alternatively be used in space systems, utilizing radiofrequency energy present in space communications.

[0028] The above-described generator **100** may also be used in combination with other power-transmitting devices. For example, the generator **100** may be used together with a traditional gas engine, electric motor, or a hybrid engine. The generator **100** may also be used in combination with other forms of alternative energy, such as solar power, wind power, or hydropower.

[0029] In the foregoing description, certain terms have been used for brevity, clearness, and understanding. No unnecessary limitations are to be implied therefrom beyond the requirement of the prior art because such terms are used for descriptive purposes and are intended to be broadly construed. The different configurations, systems and method steps described herein may be used alone or in combination with other configurations, systems and method steps. It is to be expected that various equivalents, alternatives and modifications are possible.

[0030] It should be noted that any use of the term "exemplary" herein to describe various embodiments is intended to indicate that such embodiments are possible examples, representations, and/or illustrations of possible embodiments (and such term is not intended to connote that such embodiments are necessarily extraordinary or superlative examples).

[0031] The use of the term "approximately" in relation to numbers, values, and ranges thereof refers to plus or minus five percent of the stated of numbers, values, and ranges thereof.

[0032] The terms "coupled" and the like as used herein mean the joining of two members directly or indirectly to one another. Such joining may be stationary (e.g., permanent) or moveable (e.g., removable or releasable). Such joining may be achieved with the two members or the two members and any additional intermediate members being integrally formed as a single unitary body with one another or with the two members or the two members and any additional intermediate members being attached to one another.

[0033] References herein to the positions of elements (e.g., "top," "bottom," "above," "below," etc.) are merely used to describe the orientation of various elements in the FIGURES. It should be noted that the orientation of various elements may differ according to other exemplary embodiments, and that such variations are intended to be encompassed by the present disclosure.

[0034] It is important to note that the construction and arrangement of the various exemplary embodiments are illustrative only. Although only a few embodiments have been described in detail in this disclosure, those skilled in the art who review this disclosure will readily appreciate that many modifications are possible (e.g., variations in sizes, dimensions, structures, shapes and proportions of the various elements, values of parameters, mounting arrangements, use of materials, colors, orientations, etc.) without materially departing from the novel teachings and advantages of the subject matter described herein. For example, elements shown as integrally formed may be constructed of multiple parts or elements, the position of elements may be reversed or otherwise varied, and the nature or number of discrete elements or positions may be altered or varied. The order or sequence of any process or method steps may be varied or re-sequenced according to alternative embodiments, and elements from different embodiments may be combined in a manner understood to one of ordinary skill in the art. Other substitutions, modifications, changes and omissions may also be made in the design, operating conditions and arrangement of the various exemplary embodiments without departing from the scope of the present invention.

What is claimed is:

1. An electromagnetic generator comprising:

an antenna configured to receive radiofrequency energy;

a first circuit connected to the antenna and configured to charge a first battery using the radiofrequency energy received by the antenna;

a control unit configured to receive power from the first battery and further configured to power at least one electromagnet to generate a magnetic field;

a rotatable body having at least one magnet and configured to rotate when the magnetic field is generated; and

a second circuit connected to the rotatable body and configured to supply power to an external device based on the rotation of the rotatable body.

2. The electromagnetic generator of claim **1**, further comprising a second battery, wherein the second circuit is further configured to charge the second battery based on the rotation of the rotatable body.

3. The electromagnetic generator of claim **2**, wherein the second battery is configured to supply power to the external device.

4. The electromagnetic generator of claim **1**, wherein the rotatable body is a flywheel.

5. The electromagnetic generator of claim **1**, wherein the first circuit is a rectifier.

6. The electromagnetic generator of claim **1**, wherein the second circuit is an alternator.

7. The electromagnetic generator of claim **1**, wherein the first battery comprises at least two batteries.

8. The electromagnetic generator of claim **2**, wherein the second battery comprises at least two batteries.

9. The electromagnetic generator of claim **1**, comprising three electromagnets.

10. The electromagnetic generator of claim **9**, wherein the three electromagnets are each configured to have different magnetic field strengths.

11. The electromagnetic generator of claim **1**, further comprising a cooling system.

12. The electromagnetic generator of claim **1**, further comprising a control panel configured to indicate to a user charging levels of the first battery and the second battery.

13. A method for supplying power using radiofrequency energy, comprising:

receiving radio waves through an antenna;

converting energy from the radio waves to a first current;

using the first current to charge a first battery;

powering at least one electromagnet to produce a magnetic field using energy supplied from the first battery;

rotating a rotatable body due to the magnetic field produced by the at least one electromagnet;

converting energy produced by the rotation of the rotatable body to a second current; and

using the second current to power an external device.

14. The method of claim **13**, further comprising the steps of using the second current to charge a second battery and powering an external device using energy supplied from the second battery.

15. The method of claim **13**, wherein the first battery is a plurality of batteries.

16. The method of claim **13**, wherein the rotatable body is a flywheel.

17. The method of claim **13**, wherein the first current is a direct current.

18. The method of claim **13**, wherein the second current is an alternating current.

19. The method of claim **14**, wherein the second current is a direct current.

20. An electromagnetic generator comprising:

an antenna configured to receive radiofrequency energy;

a rectifier circuit connected to the antenna and configured convert the radiofrequency energy to direct current energy used to charge a first battery;

a control unit configured to receive power from the first battery and further configured to power at least one electromagnet to generate a magnetic field;

a flywheel having at least one magnet and configured to rotate when the magnetic field is generated; and an alternator mechanically connected to the flywheel and configured to charge a second battery based on the rotation of the flywheel;

wherein the second battery is configured to supply power to an external device.

(57) **ABSTRACT**

A device for harvesting radio frequency (RF) energy to generate power includes a first spiral antenna having a first spiral direction, the first spiral antenna having a spiral cross-section shape along a first flat plane. The device includes a second spiral antenna having a second spiral direction opposite the first spiral direction, the second spiral antenna having a spiral cross-section shape along a second plane parallel to the first plane. The device further includes a ground layer between the first and second spiral antennae, the first spiral antenna electrically connected to the second spiral antenna at a center of the first and second spiral antennae by a conductive element passing through the ground layer without contacting the ground layer.

RADIO FREQUENCY HARVESTER ASSEMBLY

BACKGROUND OF THE INVENTION

[0001] Embodiments of the invention relate to radio frequency harvesters, and in particular to spiral antennae for harvesting RF signals to generate power.

[0002] Numerous methods are being developed and used to harvest non-conventional or ambient energy available in nature to power small electronic devices. Examples of non-conventional power sources include solar energy, vibration energy, radio frequency (RF) energy, heat energy, etc. Some of these energy sources are ubiquitous, while others are available only at particular times or locations.

[0003] The increasing use of wireless communication and wireless networks makes RF energy everywhere in the world. Most of the energy generated to facilitate RF communication is dissipated in the environment (e.g. air molecules, structures, organisms, etc.) Efforts are underway to capture some of this otherwise-lost RF energy to generate power.

BRIEF DESCRIPTION OF THE INVENTION

[0004] Embodiments of the invention include a device for harvesting radio frequency (RF) energy to generate power. The device includes a first spiral antenna having a first spiral direction, the first spiral antenna having a spiral cross-section shape along a first flat plane. The device includes a second spiral antenna having a second spiral direction opposite the first spiral direction, the second spiral antenna having a spiral cross-section shape along a second plane parallel to the first plane. The device further includes a ground layer between the first and second spiral antennae, the first spiral antenna electrically connected to the second spiral antenna at a center of the first and second spiral antennae by a conductive element passing through the ground layer without contacting the ground layer.

[0005] Additional embodiments include a device for harvesting radio frequency (RF) energy to generate power. The device includes a first array of spiral antennae arranged along a first flat plane and a second array of spiral antennae arranged along a second plane parallel to the first plane. The device also includes a ground layer arranged between the first array and the second array and a harvester circuit configured to receive an RF signal based on RF energy gathered by the first and second arrays of spiral antennae and to generate direct current (DC) power based on the RF signal.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] The subject matter, which is regarded as the invention, is particularly pointed out and distinctly claimed in the claims at the conclusion of the specification. The foregoing and other features, and advantages of the invention are apparent from the following detailed description taken in conjunction with the accompanying drawings in which:

[0007] FIG. **1** illustrates an antenna assembly according to an embodiment of the invention;

[0008] FIG. **2** illustrates a side view of a part of an antenna assembly according to an embodiment of the invention;

[0009] FIG. **3** illustrates interconnected spiral antennae according to an embodiment of the invention;

[0010] FIG. **4** illustrates an antenna array according to an embodiment of the invention;

[0011] FIG. **5** illustrates layers of an antenna assembly according to an embodiment of the invention;

[0012] FIG. **6** illustrates layers of an antenna assembly according to another embodiment of the invention;

[0013] FIG. **7** illustrates a first balun layer according to an embodiment of the invention;

[0014] FIG. **8** illustrates a second balun layer according to an embodiment of the invention; and

[0015] FIG. **9** illustrates a block diagram of harvester assembly according to an embodiment of the invention.

[0016] The detailed description explains embodiments of the invention, together with advantages and features, by way of example with reference to the drawings.

DETAILED DESCRIPTION OF THE INVENTION

[0017] Radio frequency (RF) energy is generated to communicate between RF devices, but the majority of RF energy is dissipated in the environment. Embodiments of the invention relate to harvesting RF energy with spiral antenna arrays.

[0018] FIG. **1** illustrates an antenna assembly **100** according to an embodiment of the invention. The antenna assembly **100** includes a layer interconnect circuit **110**, an antenna array **120** and a harvester circuit **130**. The antenna array **120** is a multi-layer antenna array, and the layer interconnect circuit **110** connects the multiple layers of the antenna array **120**. The harvester circuit **130** collects the electrical energy generated by the antenna array **120** and proves an electrical outlet to provide the electrical energy to an electrical device, such as a battery or other device that runs on electricity or stores an electrical charge.

[0019] FIG. **2** illustrates a side view of an antenna assembly **200** according to an embodiment of the invention. The antenna assembly **200** includes a first spiral antenna layer **210**, a first flat antenna layer **220**, a ground layer **230**, a second spiral antenna layer **250**, and a second flat antenna layer **260**. The first spiral antenna layer **210** includes three spiral antennae **212***a*, **212***b* and **212***c* located in openings **213***a*, **213***b* and **213***c* in a first substrate **211**. The second spiral antenna layer **250** includes three spiral antennae **252***a*, **252***b* and **252***c* located in openings **253***a*, **253***b* and **253***c* in a second substrate **251**. The three spiral antennae **212***a*, **212***b* and **212***c* are connected to the three spiral antennae **252***a*, **252***b* and **252***c* by electrical components including Schottky diodes **240***a*, **240***b* and **240***c*.

[0020] The first flat plate antenna layer **220** is formed on the first substrate **211**. The first flat plate antenna layer **220** comprises a conductive material, and a separate flat plate antenna of the flat plate antenna layer **220** may be positioned above each spiral antenna **212***a*, **212***b* and **212***c*. Similarly, the second flat plate antenna layer **260** is formed on the second substrate **251**. The flat plate antenna layers **220** and **260** will be described in further detail below with respect to FIG. **4**.

[0021] The ground layer **230** includes a substrate **231** and ground plate **232**. The ground plate **232** may be a conductive plate having holes cut into the plate to pass conductive lines connecting the first spiral antennae **212***a*, **212***b* and **212***c* and the second conductive antennae **252***a*, **252***b* and **252***c*. Since the first and second spiral antenna layers **210** and **250** are separated by a ground plate **232**, the radiation fields of the spiral antennae of the respective layers **210** and **250** are at least partially separated, and polarization loss and electromagnetic interaction loss are reduced or eliminated.

[0022] FIG. **3** illustrates connected spiral antennae **212***a* and **252***a* according to an embodiment of the invention. The spiral antennae **212***a* and **252***a* are arranged parallel to each other, and spiral in opposite directions. As illustrated in FIG. **3**, the first spiral antenna **212***a* spirals in a counter-clockwise direction (CCW) and the second spiral antenna **252***a* spirals in a clockwise direction (CW) from its center outward. In embodiments of the invention, the spiral antennae **212***a* and **252***a* connected by the Schottky diode **240***a* form a rectanna, which is an antenna that detects or receives microwaves and generates a direct current (DC) output based on the detected or received microwaves. The Schottky diode **240***a* rectifies the signals generated by the spiral antennae **212***a* and **252***a* and a load (not shown) may be connected across the Schottky diode **240***a*.

[0023] In embodiments of the invention, the spirals of the spiral antennae **212***a* and **252***a* may be Archimedean-style, single-armed spirals. Technical effects of such spiral antennae include higher spectral efficiency than other planner antennae, and the spiral antennae are frequency independent. In addition, in some embodiments the bandwidths of the spiral antennae reach up to 40:1 for both the input impedance and radiation patterns.

[0024] In addition, as illustrated in FIGS. **2** and **3**, the connected spiral antennae, such as spiral antennae **212***a* and **252***a,* result in dual polarization, which is achieved via dual planes of Archimedean spiral antennae, such as antennae **212***a* and **252***a*. In addition, as illustrated in FIG. **2**, the ground plate **232** or **272** between the connected spiral antennae electromagnetic interaction due to parallelism of spirals having opposite polarities. Further, while FIG. **2** illustrates different antennae, plates and layers of varying thicknesses, the illustrated thicknesses and sizes are for purposes of illustration only, and embodiments of the invention are not limited to sizes or proportions illustrated in FIG. **2**.

[0025] FIG. **4** illustrates an antenna array **120** according to an embodiment of the invention. The antenna array **120** includes antenna modules **410**, **420**, **430**, **440**, **450**, **460**, **470**, **480** and **490**. The antenna module **410** will be described in further detail, although the characteristics of the antenna module **410** are the same as the characteristics of the antenna modules **420**, **430**, **440**, **450**, **460**, **470**, **480** and **490**. In addition, the antenna modules **410**, **420** and **430** may correspond to the spiral antennae **212***a,* **212***b* and **212***c* of FIG. **2**.

[0026] The antenna module **410** includes a spiral antenna **411** and flat plate antennae **414** and **415**. The flat plate antennae **414** and **415** make up a portion of the flat plate antenna layer **220** of FIG. **2**. The flat plate antenna **415** includes an output connected to an adjacent flat plate antenna of the antenna module **420**, and the flat plate antenna **414** includes an output connected to a different flat plate antenna of the antenna module **460**.The spiral antenna **411** includes a first end connector **412** connected to a layer interconnect circuit **110** and a center connector **413** connected to a spiral antenna located on an opposite side of a spiral antenna assembly from the spiral antenna **411**, as illustrated in FIG. **2**.

[0027] The flat plate antennae **414** and **415**, also referred to as patch antennae **414** and **415**, capture leaky microwaves, or microwaves that may be emitted by the spiral antenna **411**. The flat plate antennae **414** and **415** have angular shapes that substantially surround the spiral antenna **411** along a circumference of the spiral antenna **411**, or in a radial direction with respect to the center of the spiral antenna **411**. FIG. **2** illustrates the flat plate antenna layer **220** located on top of the substrate **211** for purposes of description. However, embodiments encompass flat plate antennae that are inserted into grooves in a substrate **211** to have an outer surface that is substantially flush with the outer surface of the substrate **211**. The flat plate antennae **414** and **415** capture leaky waves and improve spiral antenna **411** broadband characteristics by improving a frequency vs. impedance curve of the spiral antenna **411**.

[0028] The outputs from the antenna modules **410** to **490**, including the spiral antennae **411** and the patch antennae **414** and **415** of each antenna module **410** to **490**, are output to the layer interconnect circuit **110**, which is a printed circuit in electrical communication with the array **120**. In one embodiment, the layer interconnect circuit **110** is printed on the same substrate in which the antennae modules **410** to **490** are located. The substrate **401** may be, for example, a printed wiring board.

[0029] FIG. **5** illustrates a cross-section view of layers of an antenna assembly **500** according to an embodiment of the invention. The antenna assembly includes a first spiral antenna layer **510** including a substrate **511**, spiral antennae **512***a,* **512***b* and **512***c* and patch antennae **516**. The substrate **511** may be made of any electrically insulating material, such as a printed circuit board (PCB), resin, semiconductor material, or any other electrically insulating material. The antennae **512***a,* **512***b* and **512***c* and the patch antennae **516** may be made of any conductive material, such as copper, aluminum, gold, silver, or any other conductive material or alloy. The antenna **512***a,* **512***b* and **512***c* and the patch antennae **516** may be pre-formed and deposited on the substrate **511**, may be formed by photolithography or chemical deposition on the substrate **511**, or may be formed or deposited by any other process.

[0030] Below the first spiral antenna layer **510** is a first thin dielectric layer **520**. Below the first thin dielectric layer **520** is a first balun layer **525**. The first balun layer **525** includes balun wiring **527** on a substrate **526**. Below the first balun layer **525** is a second thin dielectric layer **530**. Below the thin dielectric layer **530** is a ground layer **535**, including a conductive ground plate or wiring.

[0031] The antenna assembly **500** further includes a second spiral antenna layer **540** including a substrate **541**, spiral antennae **542***a,* **542***b* and **542***c* and patch antennae **546**. Above the second spiral antenna layer **540** is a third thin dielectric layer **550**. Above the third thin dielectric layer **550** is a second balun layer **555**. The second balun layer **555** includes balun wiring **557** on a substrate **556**. Above the second balun layer **555** is a fourth thin dielectric layer **530**. Above the fourth thin dielectric layer **560** is the ground layer **535**.

[0032] As illustrated in FIG. **5**, all of the layers **510**, **520**, **525**, **530**, **535**, **540**, **550**, **555**, and **560** have holes in them to form channels **513***a,* **513***b* and **513***c* extending between the spiral antennae **512***a* to **512***c* and the spiral antennae **542***a* to **542***c.* A rectifier **515***a,* **515***b* or **515***c* is located along wires **514***a,* **514***b* and **514***c* extending between the spiral antennae **512***a* to **512***c* and the spiral antennae **542***a* to **542***c.* In one embodiment, the rectifiers **515***a* to **515***c* are Schottky diodes. Although the rectifiers **515***a* to **515***c* are illustrated as being within the channels **513***a* to **513***c,* embodiments of the invention encompass any configuration in which the rectifiers **515***a* to **515***c* are located electrically between the spiral antennae **512***a* to **512***c* and the spiral antennae **542***a* to **542***c.* For example, the rectifiers **515***a* to **515***c* may be circuit elements mounted onto, or within, one of the dielectric layers **520**, **530**, **550**, or **560**, or mounted on the substrates **526** or **557**. In addition, while FIG. **5** illustrates a wire or line **514** extending through the channel **513***a*, embodiments of the invention encompass any method of electrical connection, such as providing a conductive filling material to fill the channels **513***a* to **513***c*.

[0033] While the connections between the spiral antennae **512***a* to **512***c* and the spiral antennae **542***a* to **542***c* are illustrated in FIG. **5**, it is understood that the antenna assembly **500** includes additional electrical and physical connections between various layers, including between the spiral antennae **512***a* to **512***c* and the first balun circuit **527**, or balun wiring layer, and between the first balun circuit **527** and the first ground plate **537**.

[0034] While the terms "above" and "below" have been used to describe the layers in view of FIG. **5**, it is understood that embodiments of the invention encompass devices having layers arranged as in FIG. **5**, but having any orientations, such as at an angle greater than zero with respect to FIG. **5**. In addition, embodiments of the invention encompass antenna assemblies having additional layers or layers omitted, relative to FIG. **5**. In one embodiment, the total thickness of the antenna assembly, such as the assembly **500** of FIG. **5**, satisfies the following: $0.006\lambda o<h<=0.05\lambda o$, where λo is the wavelength of a radio frequency (RF) wave in free space.

[0035] FIG. **6** illustrates a cross-section view of layers of an antenna assembly **600** according to an embodiment of the invention. The antenna assembly includes a first spiral antenna layer **610** including a substrate **611** and spiral antennae modules **612***a*, **612***b* and **612***c*. The substrate **611** may be made of any electrically insulating material, such as a printed circuit board (PCB), resin, semiconductor material, or any other electrically insulating material. The antennae modules **612***a*, **612***b* and **612***c* each include a dielectric insulating layer **615***a*, **615***b* or **615***c* which, together with the substrate **611**, forms a cavity **617***a*, **617***b* or **617***c*. A spiral antenna **613***a*, **613***b* or **613***c* is formed on the dielectric insulating layer **615***a*, **615***b* or **615***c*. Patch antennae **614***a*, **614***b* or **614***c* are formed to surround the spiral antenna **613***a*, **613***b* or **613***c* on the surface of the dielectric insulating layer **615***a*, **615***b* or **615***c*. The patch antennae **614***a*, **614***b* and **614***c* are also configured to surround lateral sides of the dielectric insulating layers **615***a*, **615***b* or **615***c*. In other words, a portion of the patch antennae **614***a*, **614***b* or **614***c* is located on the same surface of the dielectric insulating layers **615***a*, **615***b* or **615***c* as the spiral antennae **613***a*, **613***b* or **613***c*, and a portion of the patch antennae **614***a*, **614***b* or **614***c* is located on lateral sides of the dielectric insulating layers **615***a*, **615***b* or **615***c*.

[0036] Below the first spiral antenna layer **610** is a first thin dielectric layer **620**. Below the first thin dielectric layer **620** is a first balun layer **630**. Below the first balun layer **620** is a second thin dielectric layer **630**. Below the second thin dielectric layer **630** is a ground layer **640**, which may be a conductive plate. The antenna assembly **600** further includes a second spiral antenna layer **670** including a substrate **671** and spiral antennae modules **672***a*, **672***b* and **672***c*. The substrate **671** may be made of any electrically insulating material, such as a printed circuit board (PCB), resin, semiconductor material, or any other electrically insulating material. The antennae modules **672***a*, **672***b* and **672***c* each include a dielectric insulating layer **675***a*, **675***b* or **675***c*. A spiral antenna **673***a*, **673***b* or **673***c* is formed on the dielectric insulating layer **675***a*, **675***b* or **675***c*. Patch antennae **674***a*, **674***b* or **674***c* are formed to surround the spiral antenna **673***a*, **673***b* or **673***c* on the surface of the dielectric insulating layer **675***a*, **675***b* or **675***c*. The patch antennae **674***a*, **674***b* and **674***c* are also configured to surround lateral sides of the dielectric insulating layers **675***a*, **675***b* or **675***c*.

[0037] As illustrated in FIG. **6**, all of the layers **610**, **620**, **630**, **640**, **650**, **660** and **670** have holes in them to form channels **681**. For purposes of clarity, only the channel **681** extending between the spiral antennae **613***a* and **673***a* is labeled in FIG. **6**, but each opposing pair of antennae **613***a* and **673***a*, **613***b* and **673***b*, and **613***c* and **673***c* is connected by a conductive line **682** extending through channels **681** in the layers **610**, **620**, **630**, **640**, **650**, **660** and **670**. In one embodiment, an insulator **683** surrounds the conductive line **682** within the channel **681** at locations corresponding to the ground layer **640** and balun layers **620** and **650** to prevent electrical contact between the conductive line **682** and the layers **640**, **620** and **650**.

[0038] In one embodiment, a rectifier **616***a*, **616***b* or **616***c*, such as a Schottky diode, is electrically connected to a center of the spiral antennae **613***a*, **613***b* or **613***c*. For example, the Schottky diode may be surface mounted to the center of the spiral antennae **613***a*, **613***b* or **613***c*. The rectifier **616***a*, **616***b* or **616***c* is located along the electrical path between the spiral arms of the spiral antennae **613***a* to **613***c* and the spiral antennae **673***a* to **673***c*.

[0039] In one embodiment, the spiral antenna modules **612***a* to **612***c* and **672***a* to **672***c* are readily connectable and disconnectable from the conductive line **682**. As illustrated in FIG. **6**, the conductive line **682** has a connector **684** that is located to connect to a connector **685** of each spiral antenna module **612***a* to **612***c* and **672***a* to **672***c*. The connectors **684** and **685** may be of any connection type, such as a male-female connector in which one connector is inserted into another. In alternative embodiments, the spiral antenna modules **612***a* to **612***c* and **672***a* to **672***c* may be connected to the substrates **711** and **771** or the conductive line **682** by adhesives, soldering or any other permanent connection process.

[0040] While the various layers and other features have been illustrated in FIG. **6** with different thicknesses, it is understood that the thicknesses and lengths of materials and features of FIG. **6** are provided by way of illustration only, and embodiments of the invention are not limited to the specific widths, lengths, thicknesses or relative dimensions illustrated in FIG. **6**.

[0041] FIG. **7** illustrates a first balun layer **525** according to an embodiment of the invention. The balun layer illustrated in FIG. **7** may also correspond to the first balun layer **620** illustrated in FIG. **6**. The first balun layer **525** includes the substrate **526** and the balun wiring **527**. The balun wiring **527** may be any conductive material, such as copper, aluminum, etc. The balun wiring **527** may be printed on the substrate **526** via photolithography, etching, deposition, or any other method. The balun wiring **527** includes an input **528** from the first spiral antenna layer **510**, and in particular from the spiral antennae **512***a*, **512***b* and **512***c*. The balun wiring **527** also includes outputs **529** to a harvester circuit (not shown in FIG. **7**). The balun wiring **556** is also connected to ground, such as the ground plate **537**. The balun wiring **527** is configured to match the impedance of the spiral antennae **512***a* to **512***c* with the harvester circuit.

[0042] FIG. **8** illustrates a second balun layer **555** according to embodiments of the invention. The balun layer illustrated in FIG. **8** may also correspond to the second balun layer **660** of FIG. **6**. The second balun layer **555** includes a substrate **557** and balun wiring **556**. The balun wiring **556** includes an input

558 from the second spiral antenna layer **540**, and in particular from the spiral antennae **542***a,* **542***b* and **542***c*. The balun wiring **556** also includes outputs **559** to a harvester circuit (not shown in FIG. **8**). The balun wiring **556** is also connected to ground, such as the ground plate **566**. The balun wiring **556** is configured to match the impedance of the spiral antennae **542***a* to **542***c* with the harvester circuit.

[0043] In embodiments of the invention, the balun wirings **527** and **556** comprise an "unbalanced" port converted into two "balanced" ports. The unbalanced port can either be the input or the output as the device's balanced ports conversely can be either the output or the input. The balun wirings **527** and **556** are designed to have a precise 180-degree phase shift, with minimum loss and equal balanced impedances. The balun wirings **527** and **556** provide technical benefits of improving isolation between the antenna arrays of the antenna layers **510** and **540**, improving the impedance match between the antenna arrays and a harvesting circuit, improving balance/unbalance transformation characteristics, and decreasing noise interaction between the ports of the balun wirings **527** and **556**. The baluns **527** and **556** are configured to transfer the input power from an unbalanced line (i.e. from the spiral antennae **512***a* to **512***c* and **542***a* to **542***c*) to a balanced transmission line at the output. The balun wirings **527** and **556** comprise a quarter-wavelength transformer, two branches or delay lines and output lines.

[0044] The balun wirings **527** and **556** use electro-magnetic coupling to provide an equal level of power at both the output ports but with a phase difference of 180 degrees over a wide frequency range. The balun wirings **527** and **556** include $\lambda/4$ and $\lambda/2$ elements (where λ is the center frequency wavelength) with alternate interdigital capacitor-like structures formed by micro strip line projections from ground (such as the ground plates **537** and **566**) coupling with alternate loops of microstrip lines. For improved bandwidths multiple sections of half wavelength lines are interconnected by quarter wavelengths. The equivalent electrical model would be series inductors with parallel capacitors whose one end is connected ground. As a whole they form coupled line couplers. The coupled line couplers include of two quarter wavelength lines with capacitive coupling between them. The coupling between the two lines is the result of interaction of electromagnetic fields of each line. Using the planar parallel and series inductor and capacitor circuits to realize the effective open and short circuits respectively.

[0045] As illustrated in FIGS. **7** and **8**, the input lines **528** and **558** of the balun wirings **527** and **556** form two sets of loop elements. One set of loop elements has a constant $\lambda/4$ length, resulting in a balanced structure. The other set of loop elements has 180 degree out-of-phase structure, resulting in an unbalanced output along with pi-structure formation with unbalanced $\lambda/4$ and $\lambda/2$ elements. The resulting balun wirings **527** and **556** each have four ports, two input ports and two output ports.

[0046] Referring to FIGS. **4**, **5**, **7** and **8** the layer interconnect circuit **110** of FIG. **4** connects the outputs from the spiral antennae modules **410** to **490**, including the spiral antennae **411** and the patch antennae **414** and **415** to each other and to the balun layers **525** and **555**. In one embodiment, the outputs **412** of all of the spiral antennae **411** of each planar array **120**, are interconnected. For example, the array **120** illustrated in FIG. **4** is one array corresponding to the first spiral antenna layer **510** of FIG. **5** and the second spiral antenna layer **540** includes a similar array having spiral antenna with spirals of an opposite direction. In such an embodiment, all of the spiral antennae of the first spiral antenna layer **510** are connected to each other, and all of the spiral antennae of the second spiral antenna layer **540** are connected to each other. The outputs from the spiral antennae of the first spiral antenna layer **510** comprise one input **528** of the first balun wiring **525** and one input **558** of the second balun wiring **555**. Similarly, the outputs from the spiral antennae of the second spiral antenna layer **540** comprise one input **528** of the first balun wiring **525** and one input **558** of the second balun wiring **555**.

[0047] In one embodiment, the wiring of the interconnect circuit **110** connects the spiral antennae of the first spiral antenna layer **510** and the spiral antennae of the second spiral antenna layer **540** together in series, such that all of the spiral antennae of the antenna assembly **500** are connected in series, and ends of the spiral antennae are connected to the balun wirings **527** and **556**. Similarly, in one embodiment, all of the patch antennae **516** and **546** are connected in series, and ends of the series of patch antennae are connected to the balun wiring layers **527** and **556**.

[0048] FIG. **9** illustrates a block diagram of a harvester assembly **900** according to an embodiment of the invention. The assembly **900** includes an antenna array **901** connected to a voltage summation circuit **902**. The voltage summation circuit **902** may include an operational amplifier (op-amp). The antenna array **901** gathers energy from microwaves each antenna of the antenna array **901** transmits the gathered energy to the voltage summation circuit **902** to combine the gathered voltage into one power signal. The antenna array **901** may correspond to the antenna array **120** of FIGS. **1** and **4**, for example. The gathered energy is harvested via a resonator circuit **903** and voltage multiplier **904**, such as a two-stage Dickson Charge pump. The resonator circuit **903**, also referred to as a resonator tank, ensures that sufficient voltage swing is supplied in the power signal from the voltage summation circuit **902** to drive the rectifier stage **905**.

[0049] The resulting signal is input to a rectifier stage **905**. In one embodiment, the rectifier stage **905** includes a three or four stage rectifier circuit. Since some power loss occurs in the rectifier circuit, due to the energy required to drive the diode junction barrier, a capacitor **906** may be provided between the rectifier **905** and a voltage regulator **907**. The capacitor **906** may be selected such that the charging time of the capacitor is not more than one to three seconds, and the charge level is high. In one embodiment, multiple capacitors, or multiple super-capacitors, are connected in series. The rectifier **905** converts the RF power from the antenna array **901** to DC power. The voltage regulator **907** receives the rectified voltage from the rectifier stage **905** and outputs a regulated voltage at a predetermined level. The power from the voltage regulator **907** is output to a load, such as a battery.

[0050] In one embodiment, the harvester assembly **900** includes one or more microcontrollers configured to calculate a power input level and to auto-tune a matching circuit for available RF signals at a particular frequency.

[0051] Embodiments of the invention encompass rectanna antennae, and in particular, arrays of spiral antennae that are parallel to each other, that spiral in opposite directions and that are connected to each other. A ground plane is provided between the arrays of antennae to isolate the electric fields of the antennae. A dielectric layer is provided between the ground plane and the arrays of antennae to increase structural strength and to increase a gain vs. frequency of the assembly.

[0052] A rectifier, such as a Schottky diode, connects the centers of the spiral antennae of different arrays via a hole that extends through the antenna array assembly, including ground layers, dielectric layers and balun layers. In some embodiments, the Schottky diode itself is used for the matching and filtering of the output signal. However, in some embodiments of the invention, a transmission-line matching circuit is provided to match the optimal diode impedance for all frequencies, according to the maximum power transfer theorem.

[0053] The dimensions of the spiral antennae may be adjusted according to desired design characteristics. In one embodiment, the diameter of the rectenna elements (or spiral antennae) satisfies the following: $0.3333\ \lambda o<L<0.5\ \lambda o$), where L is the diameter of each rectenna element and λo is the free space wavelength of a radio frequency (RF) wave. To obtain a tilt beams, the outermost periphery of the rectenna array must be more than $2\lambda^8$. The tilted beam is obtained by superimposing a radiation field between a first active region, such as a spiral antenna having a circumference of $1\lambda^g$ and a second active region, such as a spiral antenna having a circumference of $2\lambda^g$. Here, λ^g=a wave length in a dielectric medium of an antenna assembly, such as the antenna assembly illustrated in FIG. **5**. In embodiments of the invention, the dielectric constant, ϵr, of the substrate in which the antennae are housed, such as the substrate **511** of FIG. **5**, satisfies the following: $0.2<\epsilon r<12$. In addition, the dielectric thickness, h, satisfies the following: $0.003\lambda o<h<0.05\lambda o$.

[0054] The number of turns of the spiral antennae depends on an antenna impedance calculation that matches with the optimal diode impedance. A spiral antenna having a larger number of turns with optimal spacing has more spectral efficiency and bandwidth. The circumference of the radiation zone determines the radiation frequency. In embodiments of the invention, the circumference of the radiation zone is greater than 2×λo, where λo is the wavelength of the RF wave in free space.

[0055] There are two possible excitations for spiral antennae: out of phase excitation (balanced) and in-phase excitation. The out of phase excitation creates the so-called normal or the first spiral mode and the in-phase excitation creates the second mode. Since the normal mode has a single lobe broadside pattern, it requires a balanced input. This can be achieved by using a broadband balun, such as the balun layers **525** and **555** of FIG. **5**.

[0056] While the invention has been described in detail in connection with only a limited number of embodiments, it should be readily understood that the invention is not limited to such disclosed embodiments. Rather, the invention can be modified to incorporate any number of variations, alterations, substitutions or equivalent arrangements not heretofore described, but which are commensurate with the spirit and scope of the invention. Additionally, while various embodiments of the invention have been described, it is to be understood that aspects of the invention may include only some of the described embodiments. Accordingly, the invention is not to be seen as limited by the foregoing description, but is only limited by the scope of the appended claims.

1. A device for harvesting radio frequency (RF) energy to generate power, comprising:

a first spiral antenna having a first spiral direction, the first spiral antenna having a spiral cross-section shape along a first flat plane;

a second spiral antenna having a second spiral direction opposite the first spiral direction, the second spiral antenna having a spiral cross-section shape along a second plane parallel to the first plane; and

a ground layer between the first and second spiral antennae, the first spiral antenna electrically connected to the second spiral antenna at a center of the first and second spiral antennae by a conductive element passing through the ground layer without contacting a ground plate of the ground layer.

2. The device of claim **1**, wherein the conductive element includes a Schottky diode.

3. The device of claim **1**, wherein the ground layer defines a third plane parallel to the first flat plane and the second plane.

4. The device of claim **1**, further comprising:

a first dielectric layer surrounding the first spiral antenna along the first flat plane; and

a first flat antenna mounted to the first dielectric layer, the first flat antenna defining a fourth plane parallel to the first flat plane.

5. The device of claim **4**, wherein the first dielectric layer has a thickness greater than a thickness of the first spiral antenna, such that the fourth plane does not intersect the first flat plane.

6. The device of claim **1**, further comprising:

a first balun layer between the first spiral antenna and the ground layer, the first balun layer electrically connected to the first spiral antenna and the ground layer; and

a second balun layer between the second spiral antenna and the ground layer, the second balun layer electrically connected to the second spiral antenna.

7. The device of claim **6**, further comprising:

a harvester circuit connected to the outputs of the first and second balun layers, the harvester circuit configured to receive a radio frequency (RF) signal gathered by the first and second spiral antennae and to generate a direct current (DC) signal based on the RF signal.

8. The device of claim **1**, wherein the first spiral antenna includes a first array of multiple first spiral antennae arranged along the same first flat plane, and

the second spiral antenna includes a second array of multiple second spiral antennae arranged along the same second plane.

9. The device of claim **8**, wherein the multiple first spiral antennae and the multiple second spiral antennae are arranged in series electrically.

10. A device for harvesting radio frequency (RF) energy to generate power, comprising:

a first array of spiral antennae arranged along a first flat plane;

a second array of spiral antennae arranged along a second plane parallel to the first plane;

a ground layer arranged between the first array and the second array; and

a harvester circuit configured to receive an RF signal based on RF energy gathered by the first and second arrays of spiral antennae and to generate direct current (DC) power based on the RF signal.

11. The device of claim **10**, wherein each spiral antenna of the first array has a first spiral direction and each spiral antenna of the second array has a second spiral direction opposite the first spiral direction.

12. The device of claim **10**, wherein the each spiral antenna of the first array is connected to a respective spiral antenna of the second array via a conductive element extending through a hole in the ground plane.

13. The device of claim **12**, wherein the conductive element includes a Schottky diode.

14. The device of claim **10**, wherein the first array includes a first dielectric layer surrounding the first spiral antennae of the first array along the first flat plane; and

an array of flat antenna mounted to the first dielectric layer, the array of first flat antennae defining a fourth plane parallel to the first flat plane.

15. The device of claim **14**, wherein the first dielectric layer has a thickness greater than a thickness of the spiral antennae of the first array, such that the fourth plane does not intersect the first flat plane.

16. The device of claim **10**, further comprising:

a first balun layer between the first array and the ground layer, the first balun layer electrically connected to the spiral antennae of the first array and the ground layer; and

a second balun layer between the second array and the ground layer, the second balun layer electrically connected to the spiral antennae of the second array.

17. The device of claim **16**, further comprising:

a first dielectric layer between the first array and the first balun layer;

a second dielectric layer between the first balun layer and the ground layer;

a third dielectric layer between the second array and the second balun layer; and

a fourth dielectric layer between the second balun layer and the ground layer.

18. The device of claim **17**, wherein the each spiral antenna of the first array is connected to a respective spiral antenna of the second array via a conductive element extending through holes in each of the ground plane, the first and second balun layers, and the first, second, third and fourth dielectric layers.

Abstract: This work presents the optimization of antenna captured low power radio frequency (RF) to direct current (DC) power converters using Schottky diodes for powering remote wireless sensors. Linearized models using scattering parameters show that an antenna and a matched diode rectifier can be described as a form of coupled resonator with different individual resonator properties. The analytical models show that the maximum voltage gain of the coupled resonators is mainly related to the antenna, diode and load (*remote sensor*) resistances at matched conditions or resonance. The analytical models were verified with experimental results. Different passive wireless RF power harvesters offering high selectivity, broadband response and high voltage sensitivity are presented. Measured results show that with an optimal resistance of antenna and diode, it is possible to achieve high RF to DC voltage sensitivity of 0.5 V and efficiency of 20% at −30 dBm antenna input power. Additionally, a wireless harvester (*rectenna*) is built and tested for receiving range performance.

Keywords: RF energy harvesting; wireless power transmission; coupled resonators; Schottky diode; RF to DC power converter; impedance matching; PI-matching; L-matching; rectenna

1. Introduction

For autonomous powering of sensor nodes in remote or inaccessible areas, wireless power transfer provides the only viable option to power them from an energy source. Due to the low power density of ambient RF at far-field from transmitters, there is a need to optimize each aspect of a wireless RF energy harvester for possible realistic applications. Today remote autonomous sensors are mostly powered by batteries, which have limited lifespan. Renewable powering has the potential to power autonomous sensors perpetually. Due to the expansion of telecommunications technology ambient electromagnetic (EM) power is among the most common sources of ambient energy. There are power transmitters/receivers scattered in practically any society, ranging from television transmission stations to cell phone transmitters and even wireless routers in our homes/offices or mobile phones. These transmitters in our environment and others which are on special dedicated frequencies produce ambient RF power (on the order of microwatts) which can be used as a source for powering remote microwatt budget sensors through wireless energy harvesting. This work presents different matching techniques based on different application requirements using Schottky diode-based RF to DC power converting circuits for wireless remote EM energy harvesting around 434 MHz and 13.6 MHz. Generalized analytical models and limitations of the matched RF to DC power converters are discussed. A wireless RF energy harvester consisting of an antenna and a matched diode rectifier is then realized and its performance tested. Passive wireless energy harvesting also finds applications in near field communications (NFC) [1], RFID tags [2–5], implantable electronics [6,7], and environmental monitoring [8], among others.

1.1. State of the Art

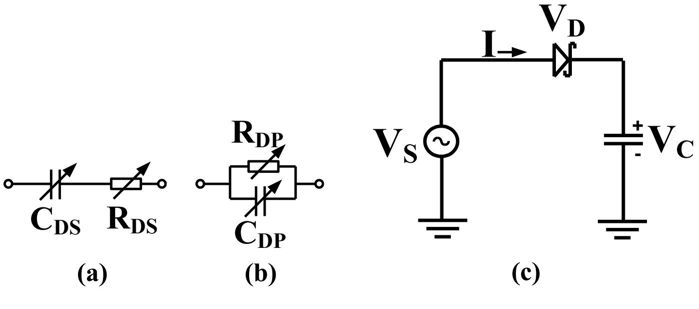
Hertz was the first to demonstrate the propagation of EM waves in free space and to demonstrate other properties of EM waves such as reflection using parabolic reflectors [9]. Wireless power transmission was then investigated and demonstrated for possible wireless remote powering by Tesla. Electromagnetic power beaming for far field wireless power transfer using collimated EM waves was proposed in the 1950s [9]. Recent advances in ultralow power sensors means ambient omni-directional EM power can be used as a source for powering remote sensors without the need to collimate the EM power through the wireless space. Mickle [10] and McSpadden [11] have presented earlier work on wireless energy harvesting systems using Schottky diodes and rectennas where the usability of ambient RF power into DC power was shown. Sample [12] presented a wireless harvester which can harvest EM power from TV and radio base stations transmitting 960 kW of effective radiated power; 60 μW was harvested at a range of about 4 km. Umeda [13] and Le [14] have presented more integrated wireless energy harvesters based on CMOS RF to DC rectifying circuits. CMOS-based rectifying power converters provide full compatibility with standard CMOS technologies and have advantages in batch processes for mass production. The drawback of CMOS-based diode connected transistors is the need to bias the gate of the transistors for the rectifying circuits to effectively function. This gate bias is provided externally, which makes the system not passive. Without the injection of external charges or a biasing of the transistor gate, the circuit has low efficiency, especially when the amplitude of the input voltage is low [15]. Shameli [2] presented a passive CMOS RF to DC power converter with a voltage sensitivity of 1 V at −14.1 dBm input, but the circuit efficiency was only 5 %. Zbitou [16] presented an RF to DC converter based on Schottky diodes and achieved 68 % efficiency at 20 dBm RF input power. Ungan [17,18] presented antennas and high quality factor RF to DC power converters at 24 MHz and 300 MHz for RF wireless energy harvesting at -30 dBm input power. The power converter used high quality factor resonators for impedance matching the EM source and the diodes and achieved high open circuit voltage sensitivity of 1 V/μW. Boquete [19] presented a risk assessment system for calculating insurance premiums by monitoring mobile phone usage while driving. This was done by harvesting EM power from detected mobile phone usage during driving for risk assessment. Heikkinen [20] presented rectennas on different substrates at 2.4 GHz using transmisson lines to match the antennas output resistance (*at resonance*) to the rectifying diodes. Akkermans [21] presented a rectenna design by complex conjugating impedance provided by a microstrip structure to a diode so that resonance may be achieved for a working frequency. This design approach may need sophisticated tools to realize and the dominant resonance frequency of the rectenna can be unpredictable in practice. Hagerty [22] presented rectenna arrays for broadband ambient EM harvesting and characterized the harvesters from 2 GHz to 18 GHz; rectennas combine impedance matching the RF rectifying circuit and the antenna into one compact device, but an array of rectennas may increase the overall size of an EM harvester. Herb [23] and Vullers [24] have provided a comprehensive state of the art for micro energy harvesting and have explored the various techniques used for harvesting ambient renewable energy.

2. RF to DC Power Converter

2.1. Diode Rectifier

A junction diode equivalent circuit and simple Schottky diode rectifier are shown in Figure 1. R_{DS} is the diode resultant series resistance, C_{DS} is the diode resultant series capacitance, R_{DP} is the diode resultant parallel resistance, C_{DP} is the diode resultant parallel capacitance, V_S is the sinusoidal source voltage and V_C is the voltage across the capacitor.

Figure 1. (**a**) Diode series equivalent model, (**b**) Diode parallel equivalent model, (**c**) Simple diode detector.



The diode capacitive impedance is mainly due to the junction capacitances provided by the metal, its passivation and the semiconductor forming the diode. AC power incident on a forward biased diode input is converted to DC power at the output. The current-voltage behavior of a single metal/semiconductor diode is described by the Richardson equation [25] as in Equation (1):

$$I = I_S\left(e^{\left(qV_D/nKT\right)} - 1\right) \tag{1}$$

where I is the current through the diode, I_S is the saturation current, q is the charge of an electron, V_D is the voltage across the diode, T is the temperature in degrees Kelvin and K is Boltzmann constant. The voltage equation around the loop can be derived from Figure 1(c) and is given in Equation (2):

$$V_D = V_S - V_C \tag{2}$$

Since the same current flows through the diode and the capacitor, one can find the average current through the circuit by integrating Equation (1) over a time period. By substituting Equation (2) into Equation (1), V_C can be expressed in terms of V_S by averaging the diode current to zero. This is given in Equation (3) [26]:

$$V_C = \frac{KT}{q}\ln\left[\vartheta_0\left(\frac{qV_S}{KT}\right)\right], \tag{3}$$

where ϑ_0 is the series expansion of the sinusoidal source voltage. Equation (3) can further be simplified for very small amplitude V_S as Equation (4):

$$V_C \approx \frac{qV_S^2}{4KT} \tag{4}$$

Equation (4) shows that for a small voltage source, the circuit output voltage is proportional to the square of the input sinusoidal voltage; hence it's so-called square law operation. Extensions of this model for voltage multipliers and other input signals are presented in [27] and [28]. Equation (4) further confirms that for low input voltage (power ≤ 10 dBm), an impedance matching network between the source and the diode is necessary to improve the detected output voltage and efficiency.

2.2. Impedance Matching

The maximum power transfer theorem states that the highest power is transferred to the load when the source resistance is the same as the load resistance. For systems with both resistive and reactive impedances from source and load, the source and the load impedance should be adjusted in a way that they are the complex conjugate of each other through impedance matching. For the purposes of this work, a 50 Ω resistive source is chosen as reference for load impedance matching. The antenna which captures the ambient RF signals is tuned to provide this source resistance at resonance for the rectifying circuit in a complete EM wireless remote harvester. The load is the resistance of the Schottky diodes and the actual connected resistance (*remote sensor*). The specific type of matching network which can be used for complex conjugation depends on the nature of load or source impedance, the desired RF to DC converter functionality and other factors like circuit size, cost, *etc.* The response of a matched RF to DC power converter depends on the matching network used as well as the source or load component quality factors and impedances.

2.3. Diode Impedance

Schottky diodes HSMS-285C and HSMS-286C from Avago [29,30] are used to build the RF to DC power converters. The HSMS-285× or 286× series diodes can be operated as zero biased with relatively low forward junction potential. This allows for the realization of completely passive RF to DC power converters for wireless energy harvesting. The HSMS-285C or 286C is a pair of series connected Schottky diodes in a SOT-323 package. The impedance of the HSMS-285C and HSMS-286C diodes was first measured so it can be matched to the resistance (50 Ω) of the antenna source. This is done by connecting the input of the diodes to a network analyzer and measuring the scattering parameters. These scattering parameters are then converted to the corresponding impedances. The input impedance of a diode depends mainly on the resistive and capacitive impedance provided by the junction of the diode and its connected load. For a couple of diodes arranged in a package such as the HSMS-285C or 286C, the input impedance is the vector sum of the impedances provided by each diode in the package arrangement, the extra impedance associated with the packaging and the connected load. The diode measuring board is as shown in Figure 2. The diodes were measured at room temperature for an input power of -30 dBm at a diode connected load of 1 MΩ with a 100 pF filter capacitor. For the sake of this work, the input impedance of the diodes will always be referred to at these connected load conditions.

Figure 2. (**left**) Reference circuit layout for measuring diodes input impedance, (**right**) measuring printed circuit board (PCB) for diodes input impedance on 1 mm FR4 substrate.

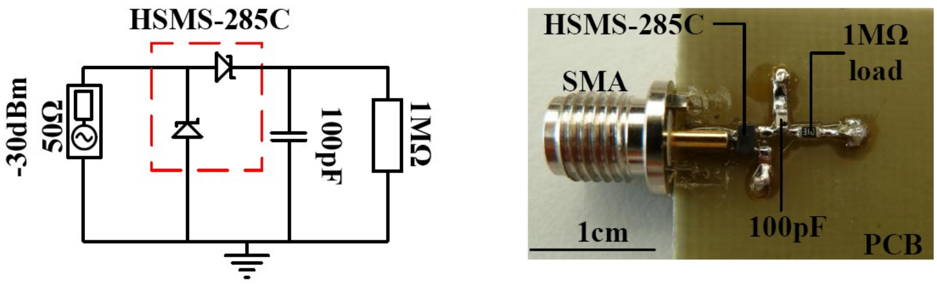


Figure 3. Measured input impedance (Δ resistive, □ capacitive) of HSMS-285C (**left**) and HSMS-286C (**right**) diodes at −30 dBm input with 1 MΩ load and 100 pF filter.

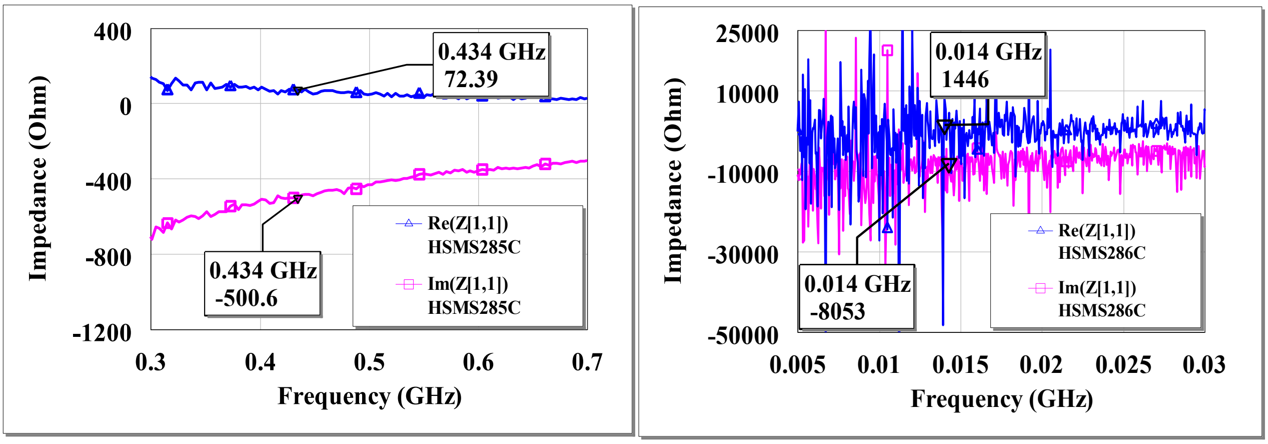

The board is fabricated such that components are soldered directly one into another to prevent additional impedances introduced by copper route. The PCB backside had the ground layer. An example of measured input impedance for HSMS-285C and HSMS-286C is shown in Figure 3.

The diodes quality factor is given by $X_{DS}R_{DS}^{-1}$, where X_{DS} is the resultant series capacitive impedance of the diodes. At an input power of −30 dBm, the measured input impedance of the HSMS-285C diodes is 72–j501 Ω at 434 MHz and 587–j1239 Ω at 13.6 MHz. For HSMS-286C diodes, it is 10–j503 Ω at 434 MHz and ~1.5–j8.1 kΩ at 13.6 MHz for −30 dBm input. The measured impedance of the HSMS-286C diodes at low frequencies (< 60 MHz) shows pronounced fluctuations. The low-frequency excess flicker noise and the shot noise observed in the HSMS-286C have been studied by several authors [31–33]. The pronounced presence of trap states in the depletion region of the semiconductor, mobility fluctuations in carriers, edge effects among other reasons is reported to cause deviations from the ideal Schottky diode behavior and hence generation-recombination noise for some diodes such as the HSMS-286C [34]. When a diode rectifier is matched at a reference operating condition, the matching network may function less effectively at other input power levels, connected load and other operating frequencies. This is due to possible changes in the diode input impedance. Throughout this work the imperfections of the matching circuit at other operating conditions away from the matched reference conditions are accepted without changes to the matching network.

2.4. Voltage Doubler

The Delon voltage doubler and Greinacher doubler are both used to realize the RF to DC power converters presented in this work. The Delon voltage doubler and Greinacher doubler are shown in Figure 4. The diodes output voltage (V_{out}) is doubled what is detected by a simple detector circuit shown in Figure 1. Both doublers produce the same output performance, the only difference is that the Delon doubler has an instantaneous input ground which is not shared with the output.

2.5. Matching Techniques for Antenna Source and RF to DC Power Converter

2.5.1. L-match RF to DC Power Converter

An L-match network converts a source series impedance to its equivalent load parallel impedance or *vice-versa* and tunes out by subtracting or adding any surplus reactance from the load or source with the counter impedance. Series impedance is converted to its parallel equivalent impedance using Equations (5–7):

$$Q_S = \frac{X_S}{R_S} \tag{5}$$

$$Q_P = \frac{R_P}{X_P} \tag{6}$$

where X_S is the total series reactive impedance, R_S is the total series resistance, R_P is the total parallel resistance, X_P is the total parallel reactive impedance, Q_S and Q_P are the series and parallel quality factors respectively:

$$R_S + jX_S = \frac{R_P \times jX_P}{R_P + jX_P} \tag{7}$$

Equation (7) is the equation of a series sum of impedances and a parallel sum of impedances. It is interesting to note that Q_S and Q_P from an L-matched network may be different from the individual component quality factors as a result of the inherent resistive and reactive impedances in that component. By virtue of Equation (7), Q_S and Q_P must be equal in an L-matched network. Using Equations (5,6) and (7), the ratio of the parallel resistance (*or reactance*) to the series resistance (*or reactance*) can be derived in terms of the quality factors Q_P or Q_S [35]. Since at match conditions, only the resistive impedances dissipate power, the loaded quality factor Q, of the L-matched network can be expressed as in Equation (8):

$$R_P = (Q^2 + 1)R_S \tag{8}$$

Using Equations (5,6) and (8), series impedance can be converted to its parallel equivalent for a fixed frequency and power level. As an example; a series impedance 72–j501 Ω (HSMS-285C at 434 MHz for −30 dBm input power) is easily converted to −*j*510(3519)/(−*j*510 + 3519) Ω as its parallel equivalent with a component quality factor of 6.96. The source resistance is taken as part of the parallel matching network in an L-match circuit if the source series equivalent resistance is greater than the load series equivalent resistance. On the other hand, the load resistance is taken as part of the parallel matching network if the load series equivalent resistance is greater than the source series equivalent resistance. For the purpose of this work, inductors were only used for series impedance matching and capacitors as shunts. This prevents power seeping through any shunt inductor used for impedance matching due the short circuit provided by a shunt inductor to ground and resulting in less output efficiency. Resistors were not used for impedance matching.

2.5.2. L-match RF to DC Converter Generalized Analytical Model

The classical matching technique using Equations (5,6) and (8) is first used to L-match the 50 Ω resistance of the antenna to the resistance of the HSMS-286C diodes (and load) at 434 MHz for −30 dBm input and then the generalized model is discussed. The antenna source resistance was L-matched to the resistance of the diodes (and load). The 50 Ω resistance of the antenna is taken as the parallel matching component and the diodes 10 Ω resistance is the series matching component. The loaded Q is found as 2 between the 50 Ω antenna source resistance and the 10 Ω diode series resistance using Equation (8). From this loaded Q, a shunt capacitive impedance of 25 Ω (14.6 pF at 434 MHz) using Equation (6) and a series inductive impedance of 20 Ω (7.3 nH at 434 MHz) using Equation (5) will match the 50 Ω source to the 10 Ω HSMS-286C diodes (and load) series resistance at −30 dBm input. Since the HSMS-286C diodes inherently provides 503 Ω series capacitive impedance at −30 dBm, a resultant series inductive impedance of 523 Ω (192 nH at 434 MHz) is needed to tune the 50 Ω resistive source to the complete HSMS-286C diodes impedance at 434 MHz for −30 dBm input. The L-matched HSMS-286C diodes rectifier is as shown in Figure 5(a).

Figure 5. (**a**) L-match RF to DC harvester using the HSMS-286C diodes at 434 MHz for −30 dBm input. (**b**) Small signal impedance model of a generalized L-matched RF to DC power converter as capacitive coupled series RLC resonator with different resonator elements.

From Figure 5(a) the power dissipated in the resistance of the diodes (and connected load); P_L is given by Equation (9), where R_L is the series resistance of the diodes and load:

$$P_L = \frac{V_L^2}{R_L} \tag{9}$$

The source power; P_S is given by Equation (10), where V_S* is the root mean squared (RMS) antenna captured source voltage. Half of the source power is transferred to the resistance of the diodes (and connected load) at match conditions as described by the maximum power transfer theorem:

$$P_S = \frac{V_S^2}{R_A} \quad \text{or} \quad P_S = \frac{V_{S*}^2}{2R_A} \tag{10}$$

Equating P_L and half RMS P_S gives a condition of maximum voltage gain for the matched RF to DC power converter shown in Figure 5(a):

$$\frac{V_L}{V_{S*}} = \frac{1}{2}\sqrt{\frac{R_L}{R_A}} \tag{11}$$

From Equation (8), substituting the series and parallel resistance ratio into Equation (11) the voltage gain can be expressed in terms of the loaded quality factor as in Equations (12) and (13), where Q is the loaded quality factor of the RF to DC power converter:

$$\frac{V_L}{V_{S*}} = \frac{1}{2}\sqrt{\frac{1}{1 + Q^2}} \tag{12}$$

Equation (12) is the voltage gain in-terms of the loaded Q if the resistance of the diodes (and connected load) is part of the series matching network and the resistance of the antenna source is part of the parallel matching network as in Figure 5(a). If the resistance of the diodes is part of the parallel matching network, then Equation (13) may be written as the voltage gain in-terms of the loaded Q in an L-matched circuit:

$$\frac{V_L}{V_{S*}} = \frac{1}{2}\sqrt{1 + Q^2} \tag{13}$$

Equations (12) and (13) shows that the maximum voltage gain is directly related to the relative differences between the diodes (and connected load) resistance and source resistance at matched conditions or the circuit loaded quality factor. It is interesting to note that the circuit shown in Figure 5(a) has a loaded Q of 2, but an HSMS-286C unloaded quality factor of 50 (at 434 MHz for −30 dBm).

Figure 5(a) is generally modeled as capacitive coupling of two series RLC resonators with a voltage source. This linearized model can be made at any defined frequency and power level. The model however neglects the metal/semiconductor physics of the diode’s junction potentials which results in a Schottky barrier. The first series RLC resonator is modeled as impedance from the antenna with or without some passive matching components. The voltage source V_S, is the antenna captured electromagnetic voltage. The second series RLC resonator is the impedance from the diodes (at a defined condition), connected resistance and some passive matching components. Ck is modeled as the coupling element between the two series RLC resonators. Figure 5(b) gives a more general look at the special scenario shown in Figure 5(a). The voltage equations in the two loops are given by Equations (14,15) according to Kirchhoff’s voltage loop laws, where ω is the angular frequency and I_1, I_2 are the currents in the first loop and second loop, respectively:

$$V_S = I_1\left[R_A + j\omega L_A - \frac{j}{\omega C_A} - \frac{j}{\omega C_K}\right] + \frac{jI_2}{\omega C_K} \tag{14}$$

$$0 = \frac{jI_1}{\omega C_K} + I_2\left[R_L + j\omega L_L - \frac{j}{\omega C_{DS}} - \frac{j}{\omega C_K}\right] \tag{15}$$

Using Cramers rule, I_2 can be expressed as:

$$I_2 = \frac{\dfrac{-jV_S}{\omega C_K}}{\left[R_A + j\omega L_A - \dfrac{j}{\omega C_A} - \dfrac{j}{\omega C_K}\right]\left[R_L + j\omega L_L - \dfrac{j}{\omega C_{DS}} - \dfrac{j}{\omega C_K}\right] + \dfrac{1}{\omega^2 C_K^2}}. \tag{16}$$

The voltage across R_L is V_L; given by I_2R_L:

$$V_L = \frac{\dfrac{-jV_S}{\omega C_K} R_L}{\left[R_A + j\omega L_A - \dfrac{j}{\omega C_A} - \dfrac{j}{\omega C_K}\right]\left[R_L + j\omega L_L - \dfrac{j}{\omega C_{DS}} - \dfrac{j}{\omega C_K}\right] + \dfrac{1}{\omega^2 C_K^2}} \tag{17}$$

The voltage gain of the coupled resonator can be expressed as in Equation (18):

$$\frac{V_L}{V_S} = \frac{\dfrac{-jR_L}{\omega C_K}}{\left[R_A + j\omega L_A - \dfrac{j}{\omega C_A} - \dfrac{j}{\omega C_K}\right]\left[R_L + j\omega L_L - \dfrac{j}{\omega C_{DS}} - \dfrac{j}{\omega C_K}\right] + \dfrac{1}{\omega^2 C_K^2}} \tag{18}$$

At resonance, there is no resultant reactance in the RLC resonators or the capacitive and inductive impedances become equal; hence Equation (19) can be written:

$$\omega L_A - \frac{1}{\omega}\left\{\frac{1}{C_A} + \frac{1}{C_K}\right\} = 0 \text{ and } \omega L_L - \frac{1}{\omega}\left\{\frac{1}{C_{DS}} + \frac{1}{C_K}\right\} = 0 \tag{19}$$

Equations in Equation (19) can be used to find the resonant frequencies of the series coupled resonator. The voltage gain of the coupled resonator at resonance can then be expressed as in Equation (20):

$$\frac{V_L}{V_S} = V_{gain} = \frac{\dfrac{-jR_L}{\omega C_K}}{R_A R_L + \dfrac{1}{\omega^2 C_K^2}} \tag{20}$$

where V_{gain} is the voltage gain. V_{gain} at resonance is a function of the resistance of the source and load and the coupling element. The maximum of Equation (20) is obtained when:

$$\frac{dV_{gain}}{dC_K} = 0. \tag{21}$$

This gives the results as in Equation (22):

$$\frac{dV_{gain}}{dC_K} = \frac{j2R_L}{\omega^3 C_K^4} - j\left\{R_A R_L + \frac{1}{\omega^2 C_K^2}\right\}\frac{R_L}{\omega C_K^2} = 0 \text{ or } R_A R_L^2 = \frac{R_L}{\omega^2 C_K^2} \tag{22}$$

Equation (22) can be simplified to find $C_{K(max)}$:

$$C_{K(\max)} = \pm\frac{1}{\omega}\sqrt{\frac{1}{R_A R_L}} \tag{23}$$

where C_{Kmax} is the value of the coupling element where maximum power transfer from the first resonator to the second resonator occurs. Using Equations (19) and (23) the unknown optimal matching impedances can be found from the known impedances just like the classical L-matched procedure using Equations (5,6) and (8). By substituting $C_{K(max)}$ into Equation (20) and taking the magnitude of V_{gain}, gives the maximum voltage gain of the coupled series resonator at resonance:

$$\left|\frac{V_L}{V_S}\right| = \frac{1}{2}\sqrt{\frac{R_L}{R_A}} \text{ or simply } \frac{V_L}{V_{S*}} = \frac{1}{2}\sqrt{\frac{R_L}{R_A}} \tag{24}$$

For wireless harvesters consisting of an antenna and a diode rectifying circuit, the diode resistive impedance at any condition is dependent on the diode realized parameters, signal frequency, connected load and the input power level. The source impedance is determined by the impedance of the antenna. For maximum efficiency, the ratio of the source resistance to the load resistance must tend to zero at matched conditions. The efficiency η of the circuit is given by Equation (25):

$$\eta = \frac{P_L}{P_S}\,;\ \eta \rightarrow 1 \ \ when \ \frac{R_A}{R_L} \rightarrow 0 \tag{25}$$

2.5.3. L-Match RF to DC Converter Experimental Results and Discussion

The presented circuit was L-matched between the 50 Ω resistance of the antenna source and the resistance of the HSMS-285C diodes (and load) at 434 MHz for −30 dBm input as shown in Figure 6. Since the series equivalent resistance of the HSMS-285C diodes and load (72 Ω) is greater than the 50 Ω series resistive antenna source, the diode is taken as parallel matching network with a parallel equivalent impedance of $-j510(3519)/(-j510 + 3519)$ Ω. The analysis follows the same procedure as in Section 2.5.2 after this step. Figure 6(b) shows the resultant L-matched RF to DC power converter. C_{DP}* is the resultant shunt matching capacitance.

Figure 6. (**a**) L-matched impedance circuit for matching the HSMS-285C diodes at 434 MHz for −30 dBm input. (**b**) Resultant network, (**c**) PCB layout of the L-matched Delon doubler with adjusted values on FR4 substrate (**d**) Fabricated PCB of the L-network matched Delon voltage doubler.

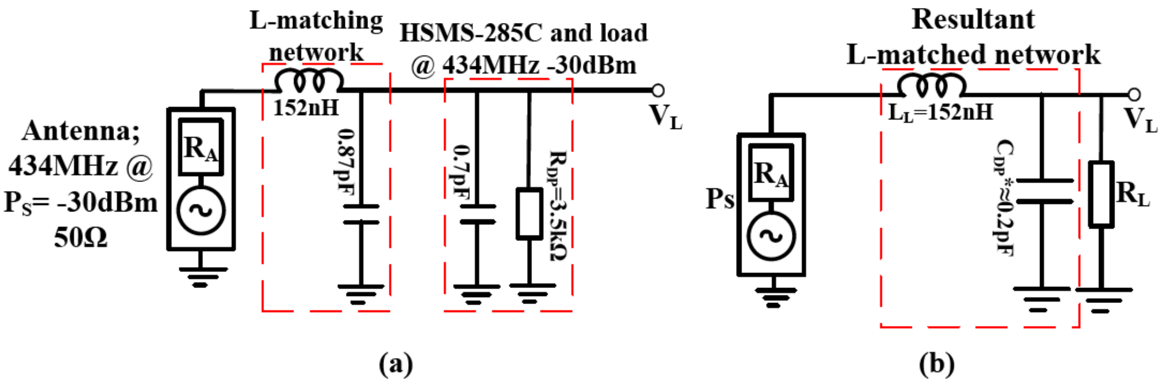

Figure 6. *Cont.*

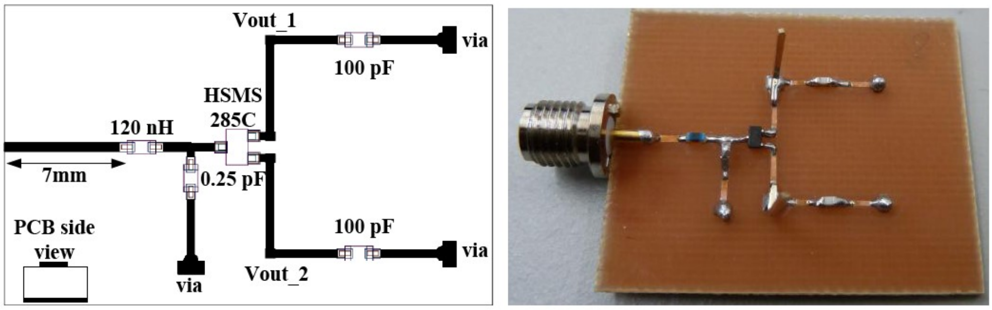


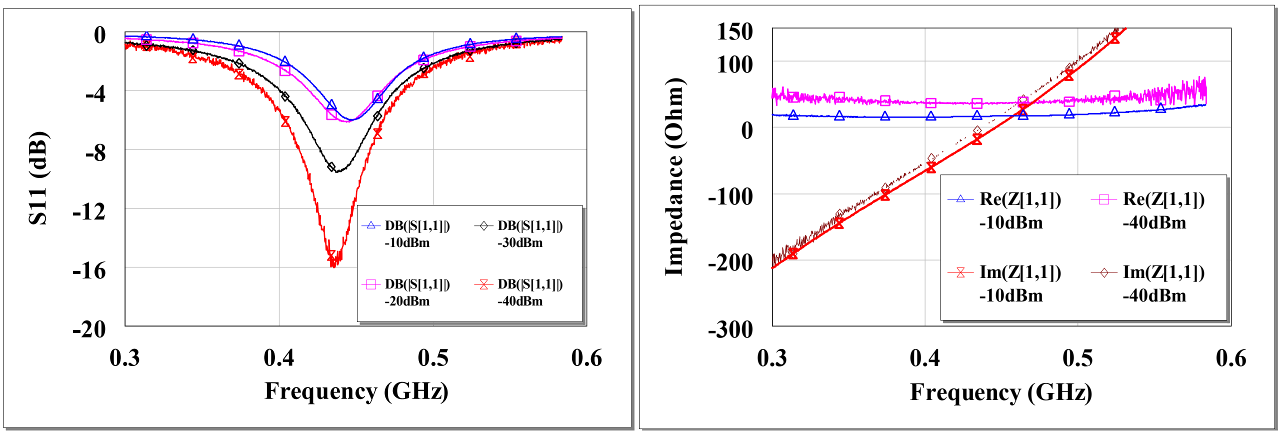
(c) (d)

Figure 6(a,b) assume perfect characteristic impedance between the various components in the matched circuit. When a copper route is introduced between components and on a material substrate, it must be accounted for in the total impedance as seen by the source or load. This PCB impedance compensation is carried out in Advance Design Systems (ADS) from Agilent [36]. ADS has extensive models for microstrip substrates to account for its impedances. The optimized layout using ADS microstrip models and its compensated values in the passive tuning components for a Delon doubler is shown in Figure 6(c).

The circuit reflection coefficient (S_{11}) and input impedance at open circuit are shown in Figure 7. There is high return loss and resonance around 434 MHz. The circuit input impedance at open circuit conditions is ~38 Ω at resonance for −40 dBm and ~17 Ω at −10 dBm input.

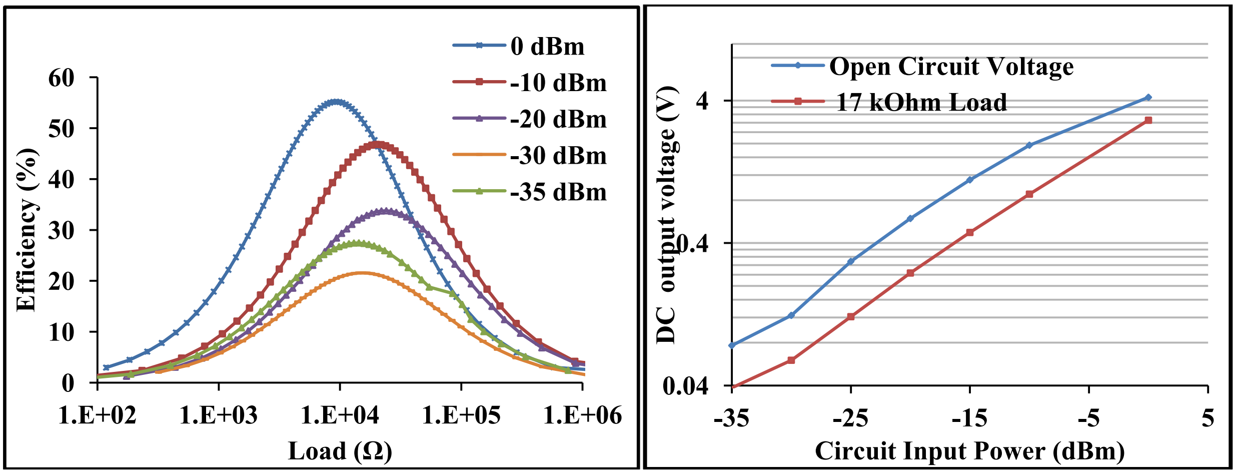
The measured L-matched circuit efficiency and voltage sensitivity is shown in Figure 8. The maximum measured L-matched efficiency at −30 dBm is 22% at ~20 kΩ load and an open circuit voltage of 124 mV. At −10 dBm, the maximum efficiency and open circuit voltage is 47% and 2 V respectively. At the optimal load of ~20 kΩ, the detected voltage is 58 mV and 1 V at −30 dBm and −10 dBm respectively.

Figure 7. Measured open circuit S_{11} of the L-matched Delon circuit at different input power levels from a 50 Ω source (**left**), measured open circuit input impedance at −10 dBm and −40 dBm of the L-matched circuit (**right**).



The open circuit voltage gain is 25 at −30 dBm and 40 at −10 dBm. The maximum measured efficiency at −35 dBm is 27%. This is higher than that of −30 dBm due to the better matched circuit impedance at −35 dBm (35 Ω) than at −30 dBm (27 Ω) input. The L-matched RF to DC power converter has a loaded *Q*, sensitivity and efficiency determined mainly by the diodes resistance, diodes junction potential, connected resistance and antenna source resistance at matched conditions.

Figure 8. Measured L-matched circuit efficiency *versus* resistive load at various input power levels at 434 MHz (**left**), measured open circuit voltage and at 17 kΩ load *versus* input power at 434 MHz (**right**).



2.5.4. PI-match RF to DC Power Converter

A highly selective or small frequency bandwidth RF power converter is realized with a PI-network in-between the source impedance from the antenna and the diode rectifier. A PI-network is a ‘back to back’ L-network that are both configured to match the load and source impedance to an invisible resistance located at the junction between the two L-networks [37]. The quality factor of the L-network with the parallel resistance is given by Equation (26):

$$Q_P^* = \sqrt{\frac{R_P}{R^*} - 1}, \tag{26}$$

where R_P is the parallel resistance, R^* is a virtual resistance and Q_P^* is the quality factor of the L-network with the parallel resistance. The quality factor of the L-network with the series resistance is given by Equation (27):

$$Q_S^* = \sqrt{\frac{R_S}{R^*} - 1}, \tag{27}$$

where Q_S^* is the quality factor of the L-network with the series resistance. The unloaded quality factor; Q_S^* or Q_P^* is set higher than what is normally achieved with a single L-network [37] to realize the small frequency bandwidth circuit. The resistance of the load is assigned the parallel network in a PI-matched circuit if its series equivalent resistance is higher than the source series equivalent resistance; the opposite is true if the source is higher than the load. Equation (26) and Equation (27) are synonymous to Equation (8), except the lowest resistive impedance in Equation (8) is substituted with the virtual resistance which is dependent on the newly desired circuit selectivity. From Equations (26) and (27) the loaded quality factor of the PI-matched circuit can be written as Equation (34) in terms of Q_S^* and Q_P^*:

$$Q^2 = \left[\left(\frac{Q_P^{*2} + 1}{Q_S^{*2} + 1}\right) - 1\right], \tag{28}$$

where Q is the loaded quality factor of the PI-network. Q_S* or Q_P* are the unloaded quality factors of the PI-matched network. The larger value among the unloaded quality factors result in small frequency bandwidth response which is desired when matching a source and load impedance with a PI-network. Some authors approximate the highest value of Q_S* or Q_P* or their algebraic sum as the loaded quality factor of the PI-network as in [35] and [37], but Equation (28) gives the exact loaded Q of the PI-matched circuit in terms Q_S* and Q_P*. This allows for the correct estimation of the maximum voltage gain from the loaded quality factor.

2.5.5. Selectivity RF to DC Converter Generalized Analytical Model

An example of a PI-matched RF to DC converter using the HSMS-285C diodes operating at 434 MHz for −30 dBm input is presented first and then the generalized model is discussed. The circuit is matched for Q_P* of 60 between the antenna and the resistance of the diodes as shown in Figure 9.

Figure 9. Impedance diagram of PI-matched RF power converter; (**a**) Impedance diagram of 50 Ω source and the HSMS-285C diodes at 434 MHz, (**b**) Resultant PI matched network between the antenna source and load resistance.

Figure 9(b) can also be modeled as an inductive coupling of two parallel RC circuits. A more general look at such a circuit is shown in Figure 10, as an inductive coupling of two parallel RLC resonators with a current source.

The first parallel RLC resonator is modeled as impedance from the antenna and some passive matching components. The second parallel RLC resonator is modeled as impedance from the linearized diodes, its connected load and some passive matching components. I is the antenna induced current, V_S this time is the voltage across the parallel R_A and K_1 is the coupling element between the two parallel resonators. Using Kirchoff's current laws, the node equations can be expressed as Equations (29) and (30):

$$I = V_S\left[\frac{1}{R_A} + j\omega C_A - \frac{j}{\omega L_A} - \frac{j}{\omega K_1}\right] + \frac{jV_L}{\omega K_1} \tag{29}$$

$$0 = \frac{jV_S}{\omega K_1} + V_L\left[\frac{1}{R_L} + j\omega C_{DP} - \frac{j}{\omega L_L} - \frac{j}{\omega K_1}\right] \tag{30}$$

Load voltage (V_L) and the source voltage (V_S) at resonance are given by the equations in Equation (31). The resonance frequencies are given by Equation (32):

$$V_L = \frac{\frac{-jI}{\omega K_1}}{\left[\frac{1}{R_A R_L} + \frac{1}{\omega^2 K_1^2}\right]} \quad \text{and} \quad V_S = \frac{\frac{I}{R_L}}{\left[\frac{1}{R_A R_L} + \frac{1}{\omega^2 K_1^2}\right]} \tag{31}$$

$$\omega C_A - \frac{1}{\omega}\left\{\frac{1}{L_A} + \frac{1}{K_1}\right\} = 0 \text{ and } \omega C_{DP} - \frac{1}{\omega}\left\{\frac{1}{L_L} + \frac{1}{K_1}\right\} = 0 \tag{32}$$

From V_L and Vs in Equation (31), the voltage gain at resonance can be expressed as:

$$\frac{V_L}{V_S} = \frac{R_L}{j\omega K_1} \tag{33}$$

The maximum of Equation (33) is obtained when:

$$j\omega K_1 \to 0 \quad or \quad R_L \to \infty \tag{34}$$

Since $j\omega K_1$ is restricted by the conditions in Equation (32) to attain resonance, one cannot manipulate $j\omega K_1$ alone without changing the resonance conditions. What can drive the voltage gain is if R_L is very large at resonance conditions. If the input impedance (V_S/I) of the coupled resonator is maximum at resonance, conditions in Equation (35) hold:

$$\left(\frac{Vs}{I}\right) \to maximum \;\; when \;\; \frac{R_L}{\omega^2 K_1^2} \to 0 \tag{35}$$

Equation (36) may be assumed when $\frac{R_L}{\omega^2 K_1^2} \to 0$:

$$\frac{V_S}{I} = R_A \tag{36}$$

Under these conditions and an optimal coupling coefficient K_{1max}, the maximum voltage gain of the parallel coupled resonator can be written as in Equation (37), where K_{1max} is given by Equation (38):

$$\left|\frac{V_L}{V_S}\right| = \left|V_{gain}\right| = \left|\frac{1}{2}\sqrt{\frac{R_L}{R_A}}\right| \tag{37}$$

$$K_{1(\max)} = \mp\frac{1}{\omega}\sqrt{R_A R_L} \tag{38}$$

The analysis of Section 2.5.2 and parallel coupled RLC resonators show that any antenna and matched rectifying diode can be described as an equivalent circuit of a coupled resonator at a defined operating point. This general model can be applied to optimize other harvesters with complex output impedance such as piezo-harvesters or vibration harvesters for maximum transfer of power or voltage to its connected load. The model can also be applied to near field magnetically coupled antennas/coils for optimization.

2.5.6. Broadband RF to DC power converter

A broadband network is preferred when an RF to DC power converter is to be operated for a wide range of frequencies. A broadband converter is realized by connecting successive L-networks together in a multi-network between the antenna source and the rectifying diodes. The result is broadband or multiband RF power converter around certain frequencies. This can be deduced from the general model of a coupled resonators that by choosing certain passive components between a source and the load, it is possible to have more frequencies (ω) fulfilling Equation (32) and hence a result of multiple resonant frequencies or broader bandwidth at match conditions. For a two stage L-connected match, the quality factor of the L-network with the parallel resistance is given by Equation (39):

$$Q_P^{\ *} = \sqrt{\frac{R_P}{R^*} - 1} \tag{39}$$

The quality factor of the L-network with the series resistance is given by Equation (40):

$$Q_S^{\ *} = \sqrt{\frac{R_*}{R_S} - 1} \tag{40}$$

From Equations (39) and (40) the loaded quality factor of the two stage L-connected broadband network may be written as Equation (41) in terms of the unloaded quality factors; Q_S* and Q_P*:

$$Q^2 = \{(Q_P^{*2} + 1)(Q_S^{*2} + 1)\} - 1 \tag{41}$$

$R*$ in this case may be chosen if it is larger than R_S and lower than the R_P. The highest possible bandwidth between a resistive source and resistive load is found for a virtual resistance ($R*$) given in Equation (42) [37]:

$$R^* = \sqrt{R_S R_P} \tag{42}$$

For complex loads such as rectifying diodes or transistors, the largest achievable bandwidth prescribed by Equation (42) is limited by the load or source component quality factor, since Equation (42) does not take into account reactive impedance associated with the source or load.

2.5.7. Broadband-Match RF to DC Converter Results and Discussion

The antenna source resistance was broadband matched to the HSMS-285C diodes (and load) resistance at −30 dBm input around 434 MHz. For a desired Q_P* and Q_S* of 2.7 there is ~0.4 pF inherent diode capacitance which is un-tuned using a two stage L-matching network [Figure 11(b)]. This is because the HSMS-285C diodes provides an inherent component quality factor of 6.96 at 434 MHz for −30 dBm input, hence a broadband circuit with Q_P* lower than this inherent component quality factor of the diodes (and load) is difficult to achieve without trade-offs. However, connected L-networks with Q_P* as high as the diode component quality factor may perform worse than a single L-matched network with similar loaded quality factor. This is due to redundant components of the connected L-networks which have inherent losses.

Figure 11. Impedance diagram of broadband RF power converter; (**a**) Broadband match around 434 MHz with loaded Q of 2.7, (**b**) Resultant impedance matching network with un-turned capacitance of 0.4 pF.

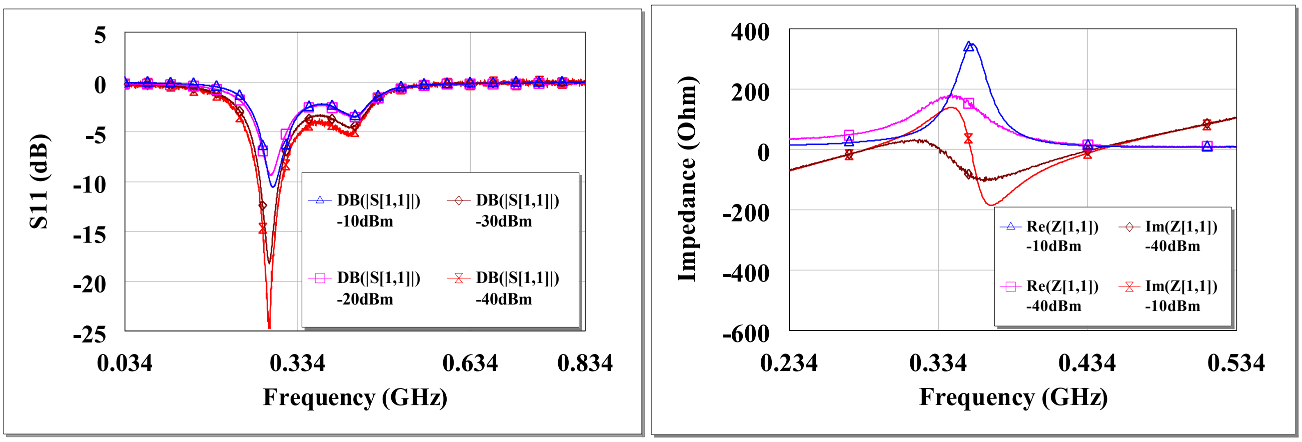
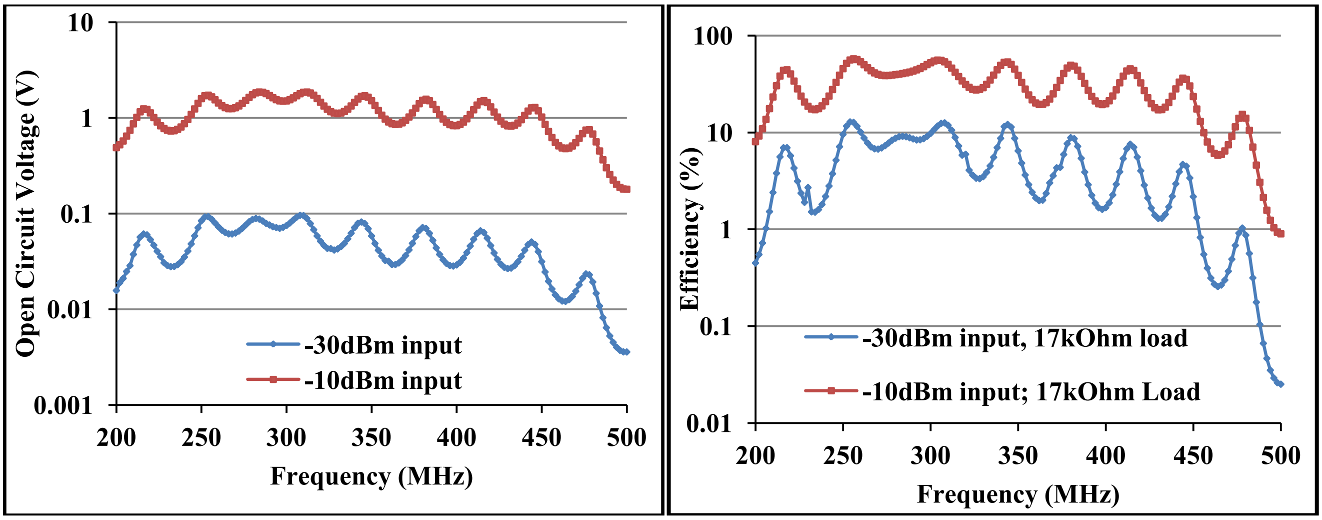
Figure 12. Measured open circuit S_{11} of the broadband circuit around 434 MHz at different input power levels from a 50 Ω source (**left**), measured open circuit input impedance at −10 dBm and −40 dBm of the broadband circuit (**right**).



Therefore the broadband circuit is matched for Q_P* of 2.7, notwithstanding the un-tuned shunt capacitance as can be seen in Figure 11(b). Figure 12 shows the circuit S_{11} at various input power levels and input impedance at open circuit conditions. From Figure 12 (left) there is ~−5 dB return loss from 200 MHz to 500 MHz providing an operating band of ~300 MHz. The impedance of the circuit shows resonances at ~290 MHz and ~450 MHz as shown in Figure 12(right). A third resonance occurs around 356 MHz at −10 dBm as the frequency of highest harvester input resistance (~350 Ω) and where the reactive impedances approach their extremes. Figure 12 show that a wireless EM harvester can exhibit different resonance scenarios depending on the dominant instantaneous conditions. The efficiency and voltage sensitivity of the broadband matched wireless EM harvester are shown in Figure 13. The average open circuit voltage is 47 mV and 1.1 V at −30 dBm and −10 dBm, respectively, when operating from 200 MHz to 500 MHz.

Figure 13. Measured open circuit voltage *versus* frequency sweep from 200 MHz to 500 MHz for −10 dBm and −30 dBm (**left**), measured efficiency at 17 kΩ load *versus* frequency sweep for −10 dBm and −30 dBm (**right**).



The broadband circuit achieves average efficiency of 5% at 17 kΩ load for −30 dBm and 30% at 17 kΩ load for −10 dBm input power from 200 MHz to 500 MHz. Figure 13 further confirm a direct link between frequency response and the unloaded quality factors. For Q_S* and Q_P* of ~2.7, the circuit response is broadband around 434 MHz.

2.6. High Voltage Sensitive RF to DC Converter

The current state of the art low power remote sensors would require a DC voltage supply of about 1 V and DC current of about 30 µA for operation. Therefore, the issue is not only how efficient a wireless EM harvester is in converting RF to DC power, but also what the output DC voltage and current of the EM harvester are at the RF input power level [38]. Equations (11,24) and (33) show that the maximum voltage sensitivity of a coupled resonator system or an RF to DC power converter is mostly related to the load and the source resistances at resonance. Therefore high voltage sensitive wireless EM harvester can be achieved with a diode voltage doubler with a very high input resistance relative to the antenna source without the need to cascade the diodes as in voltage multipliers. If the diodes been used for the RF to DC power conversion cannot provide high resistive impedance at the working frequency relative to the antenna source, then a DC-DC converter can be applied after the EM harvester as presented in [39] or the diodes may be cascaded by way of multipliers as presented in our earlier work [40] and by several other authors [3,5,14]. In case of multipliers, the input voltage ought to be high enough to overcome the junction potential of the several diodes in the multiplier network. If frequency is not a constraint, then a frequency sweep *versus* impedance for the diodes can be made and the frequency where the diodes exhibits high resistive impedance can be used to realize high voltage sensitive wireless RF harvester. For Schottky diodes, high resistive impedance occurs mostly at lower frequencies (see Figure 3). The measured voltage gain of a high resistive diode pair (voltage doubler) is presented in the next results.

2.6.1. High Voltage Sensitive RF to DC Converter Results and Discussion

The presented result was L-matched using 50 Ω resistance of the antenna source and the resistance of the HSMS-286C diodes (and load). The HSMS-286C diodes do provide high resistive impedance at low frequencies; notwithstanding the flicker noise which causes its resistive (and reactive) impedance to fluctuate. The HSMS-286C has low forward junction potential (~350 mV at 1 mA) per diode and series impedance of ~1.5–j8.1 kΩ or parallel impedance of ~$-j8.3(46.3)/(-j8.3 + 46.3)$ kΩ at 13.6 MHz for −30 dBm input. Even though the HSMS-286C diodes unloaded component quality factor at 13.6 MHz is similar to that of the HSMS-285C diodes at 434 MHz, the elevated resistive impedance at 13.6 MHz fulfills the condition for high voltage sensitivity relative to a 50 Ω antenna source at resonance conditions.

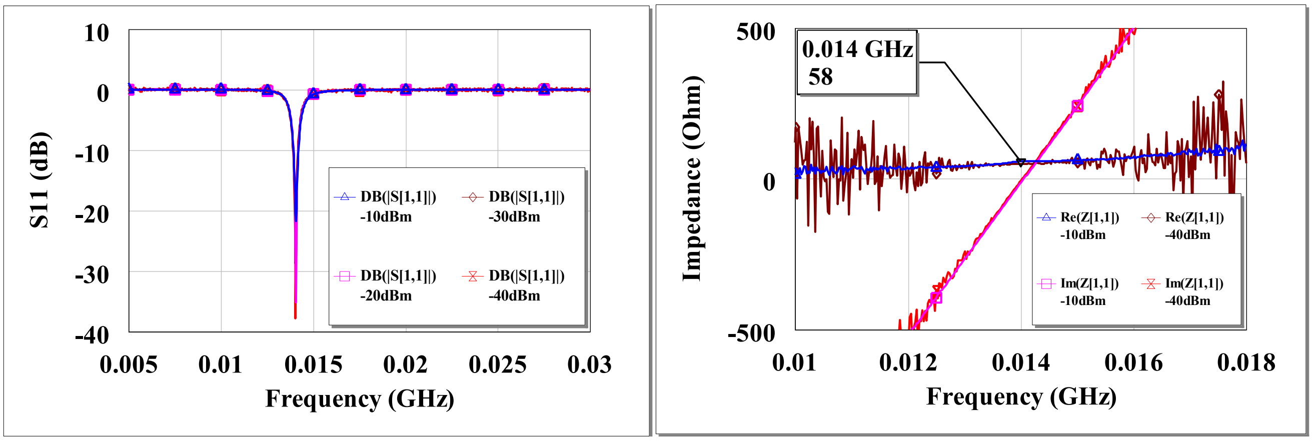
The high voltage sensitive EM harvester operating at 13.6 MHz is as shown in Figure 14. On the realized PCB is a Greinacher doubler. An inductance of 15 µH and a shunt capacitance of 5.6 pF were the adjusted values after the microstrip contributions.

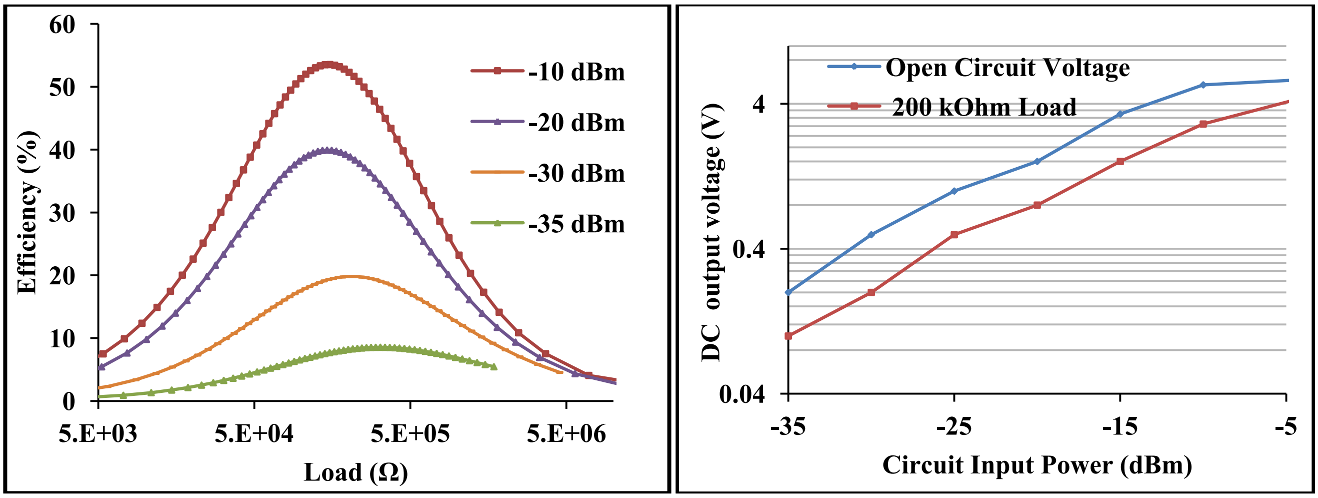
The measured S_{11} and input impedance at open circuit are shown in Figure 15. There is high return loss and resonance around 13.6 MHz. The circuit input impedance at open circuit conditions is 58 Ω at resonance for both −40 dBm and −10 dBm.

Figure 15. Measured open circuit S_{11} of the L-matched HSMS-286C diodes at 13.6 MHz for different input power levels from a 50 Ω source (**left**), measured open circuit input impedance at −10 dBm and −40 dBm of the L-matched HSMS-286C diode at 13.6 MHz (**right**).



The efficiency and voltage sensitivity of the high voltage sensitive wireless EM harvester are shown in Figure 16.

Figure 16. Measured circuit efficiency *versus* load at various input power levels at 13.6 MHz (**left**), measured open circuit voltage and at 200 kΩ load *versus* input power at 13.6 MHz (**right**).



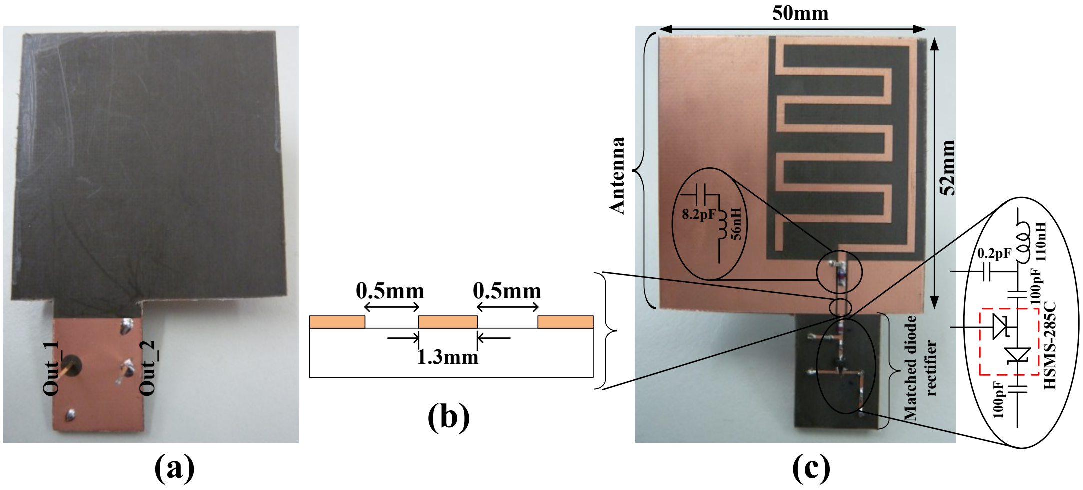
The maximum measured efficiency at −30 dBm is 20% for ~200 kΩ load and an open circuit voltage of 0.5 V. At −10 dBm, the maximum efficiency and open circuit voltage are 54% and 5.4 V respectively. At the optimal load of ~200 kΩ, the detected voltage is 0.2 V and 2.9 V at −30 dBm and −10 dBm respectively. The open circuit voltage gain is 100 at −30 dBm and 108 at −10 dBm.

Even though the RF to DC converter presented in Section 2.5.3 is the same as the L-match circuit realized with the HMSM-286C diodes at 13.6 MHz, the voltage gain is increased by a factor of 4 due to the large difference between the diodes (and load) resistance and source resistance so that at matched conditions high voltage gain occurs. The loaded *Q* of the L-matched circuit is 30 which results in small frequency bandwidth just like a PI-matched diode rectifier presented in our earlier work [40]. From this result and the results from our earlier presented PI-matched EM harvester, it can be inferred that all high loaded *Q* RF to DC circuits have high selectivity but not all highly selective RF to DC circuits have high loaded *Q*. The voltage sensitivity of the matched HSMS-286C diode at 13.6 MHz can be improved if its resistive impedance is not lowered by the flicker noise.

3. Wireless EM Power Harvester

A wireless EM harvester, consisting of a rectifying antenna (*rectenna*) was designed to find a compromise between size and performance of its antenna. The rectenna is shown in Figure 17.

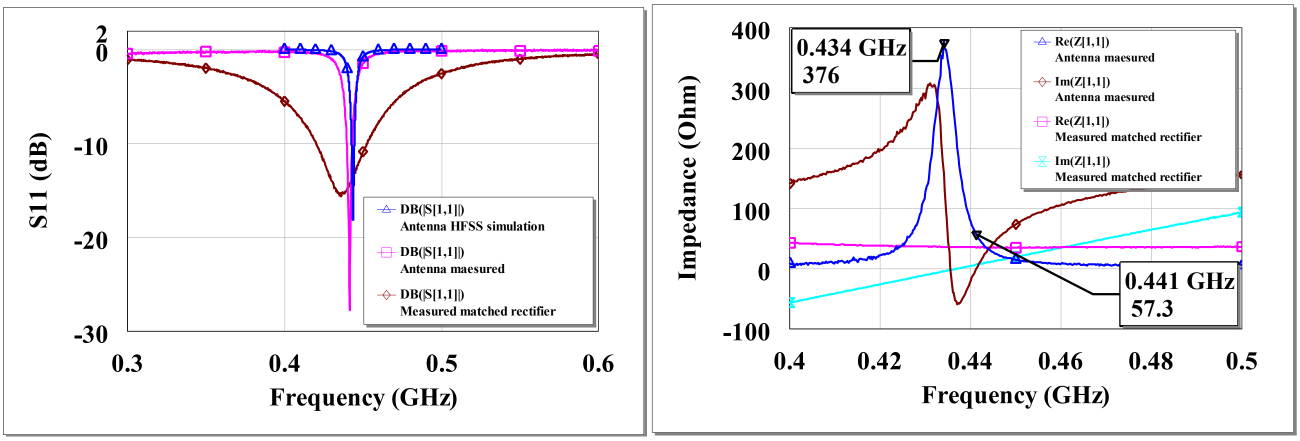
Figure 17. Rectenna realized on a Duroid 5880, 1.57 mm substrate. (**a**) Backside of the rectenna, (**b**) cross-section of antenna output coplanar stripline dimensions (**c**) frontside of the rectenna.



The antenna (planar) part of the rectenna is based on our earlier work [41]. In contrast to the earlier presented antenna, this rectenna is realized on a Duroid [42] substrate of thickness 1.57 mm. Duroid 5880 has lower loss tangent of 0.0004 at 1 MHz compared to 0.025 at 1 MHz for FR4. This means there is less loss in the transmission of signals on a Duroid PCB at this frequency range. The antenna part is fabricated to resonate around 434 MHz; hence its dimensions of 5 × 5.2 cm make it electrically small. The antenna is tuned with a chip inductor and a capacitor to achieve the resonance frequency around 434 MHz [Figure 17(c)]. This is done at a cost of reduced antenna radiation efficiency. An antenna is one of the few components the size of which is related to the operating frequency. Thus, if the size of an antenna is fixed, resonance frequency reduction of the antenna can only be achieved with penalty factors [10]. The antenna's output impedance is tuned with the dimensions of the coplanar stripline as shown in Figure 17(b).

HFSS [43] was used to simulate the presented antenna and to find the correct capacitive and inductive components for frequency tuning before the optimized design was fabricated. The simulated antenna resonances occur at 438 MHz and 445 MHz. At these frequencies, the radiation efficiency is 20% and a peak gain of −6 dBi. The rectifying part of the rectenna consists of L-matched HSMS-285C diodes (Figure 17(c)). The L-matched HSMS-285C part of the rectenna can be engineered to be as small as possible if required. The separate parts of the rectenna were characterized by terminating their ends and measuring the individual reflection coefficients just like the power converters presented in Section 2. Figure 18 shows the measured antenna and matched rectifier individual S_{11} and impedance. Figure 18 (left) also show the HFSS simulated S_{11} results. From Figure 18 (right), the measured antenna resonance where the input impedance is at maximum is ~434 MHz. At ~434 MHz, the antenna input resistance is 376 Ω and the reactive impedances approach their extreme (*so called anti-resonance*). The other resonance occurs when the input resistance is 'finite' and the reactive impedance is zero; at ~441 MHz. The input resistance is 57 Ω at ~441 MHz. The rectifier circuit is matched for the antenna's resistance at ~441 MHz.

Figure 18. Antenna HFSS simulated, antenna measured, and measured L-matched diode rectifier S_{11} on a Duroid 5880 PCB for −30 dBm input (**left**), Measured open circuit input impedance of antenna and rectifier at −30 dBm input (**right**).



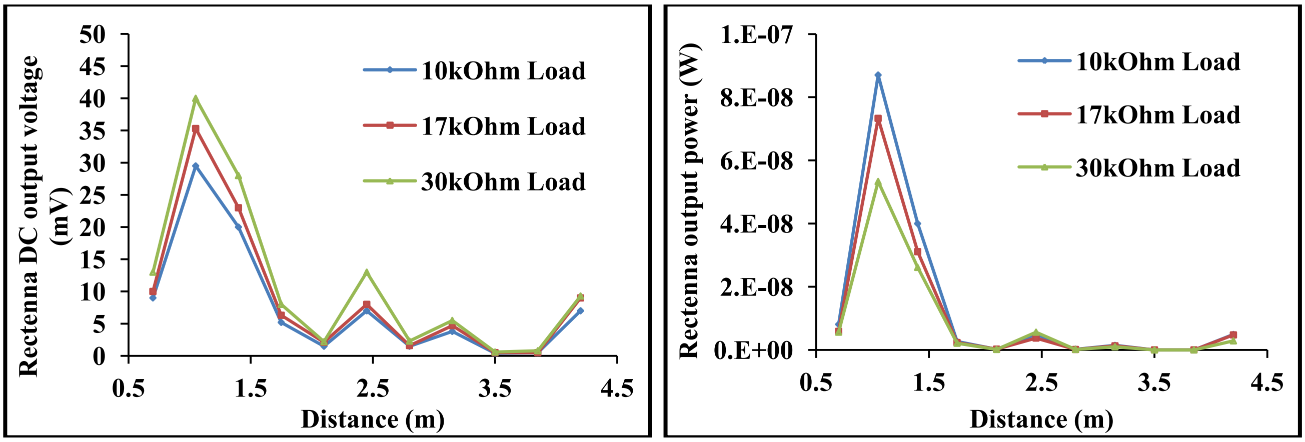
3.1. EM Range Results and Discussion

At far field between wireless EM transmitting and receiving antenna, the coupling mechanism between the transmitting and receiving antenna is neither capacitive nor inductive as is the case for the RF to DC converters. The coupling is radiative which can be described by the Friis equation of transmission on the assumption that the transmitting and receiving antenna are in free space [44]. A modified Friis equation for a transmitting and receiving antenna at far-field (R >> λ and R >> transmitting antenna largest dimension) to each other at a specified direction is given by Equation (43) [45]. Equation (43) assumes real world open space conditions:

$$\frac{P_r}{P_t} = F_{envt} G_t G_r \left(\frac{\lambda}{4\pi R} \right)^2 , \tag{43}$$

where *Pr* is the power at the receiving antenna port, *Pt* is the power supplied at the transmitting antenna port, F_{envt} is a factor accounting for environmental effects as such ground reflections among others, *Gt and Gr* are the transmitting and receiving antenna gain (*at specified direction*) respectively. *R* is the distance between the transmitting and receiving antenna and λ is the wavelength of the transmitting EM wave. The rectenna receiving range measurements were carried out in an open space (*hall*) with the antennas 2 m above ground level. The transmitting and receiving antennas were arranged in the direction of their peak gain. The rectenna range performance is shown in Figure 19. According to Equation (43), the efficiency of RF power transferred between a sending and receiving antenna depends on controllable factors like the gain of the antennas in the arranged direction and the radiation efficiency of the antennas. Since the receiving/transmitting antenna's incorporated in remote harvesters for sensor powering are normally small in relation to their operating frequencies, they tend to be less efficient.

Figure 19. Rectenna receiving range performance by sending 17 dBm (50 mW) at a gain of −6 dBi at 437 MHz. Output DC voltage *versus* receiving distance for different loads (**left**), loads output power *versus* receiving distance (**right**).



The efficiency of the rectenna's antenna is ~20% at resonance. A 'perfectly' matched RF to DC power converter operating in its square law region has efficiencies in the region of 20% as depicted in Section 2. The transmitting antenna was the same as the antenna incorporated in the rectenna. By transmitting the EM power with a small antenna (5 cm × 5.2 cm) at 437 MHz with efficiency of ~20% and at a gain of −6 dBi, the power delivered by the rectenna is generally low at far-field from the transmitter as can be seen in Figure 19. A mediocre transmitting antenna was used to transmit the EM waves due to limitations in the European Union about transmitting EM power at certain frequencies; so the goal in the rectenna range experiment is to show the lowest limit functionality of such a harvester. At 4.2 m from the electrically small transmitting antenna transmitting at 17 dBm, the rectenna harvested DC voltage and power are 9 mV and 5 nW respectively for 10 kΩ load. It can be seen from Figure 19 that the harvested voltage/power generally degrades as an inverse square of distance from transmitter as described by Friis equation. The measured received power however alternate along this R^{-2} fit as shown in Figure 19. This anomaly is accounted for by F_{envt} [Equation (43)] as influence of ground reflections and polarization in real world open field measurements [45]. For any particular distance *R*, the signals reflected from ground can be constructive with the direct signal to the rectenna, in which case the measured power may be higher than that predicted by the original Friss equation as in [44]. The ground effect can also be destructive, in which case the measured power will be lower than what is predicted by the original Friis equation.

4. Conclusions

Optimization of Schottky diode-based RF to DC power converters using different matching techniques for wireless EM energy harvesting applications is presented. Using scattering parameters for small signal modeling, it is shown that wireless EM harvesters can be generally described as coupled resonators with efficiencies and maximum voltage sensitivity depending mostly on the source and load resistances under matched conditions. The analytical models allow systematic control in the design of passive wireless EM harvesters. Based on these analyses, a rectenna is built and tested for lower limit functionality from harvesting ambient EM waves. The analysis presented in this work may also be applied to optimize derivatives of wireless EM harvesters like RFID tags, NFC, wireless chargers *etc.*, for efficient powering of their sensors or integrated circuits. Generally, most energy harvesters and their matched loads can be described as coupled resonators and thus may be optimized with the methods presented in this work.

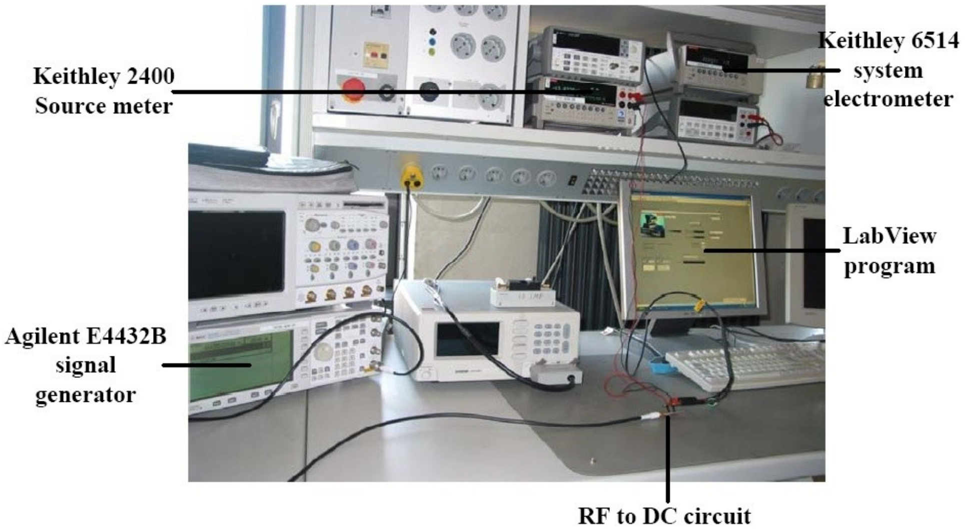
Appendix A: Measuring Setup for RF Rectifier Efficiency and Voltage Sensitivity

The measuring setup is as shown in Figure A1.

Figure A1. RF to DC Power converter characterization setup.



The RF to DC circuit efficiency and voltage sensitivity measurements were made with a Keithley 2400 source meter and Keithley 6514 system electrometer with an Agilent E4432B signal generator providing 50 Ω RF signal into the circuit board.

The closed circuit current drawn by the RF to DC power converter (*without load*) from the generator is first determined by the Keithley 2400 source meter; then starting from this current, the value of the current is decreased at set intervals to creates virtual load resistances to the circuit for up to a lowest current of 0.1 μA. The 6514 system electrometer is used to measure the output voltage. The number of data point is set through LabView [46] as well as the measurements. Additionally open circuit voltage or at specific loads and frequency sweep can be made through the LabView program. At −40 dBm input power and below, the detected voltages and currents were difficult to measure accurately with the measuring setup; hence measurements were made up to a minimum of -35 dBm input power. The circuit layout for the efficiency and voltage sensitivity measurements is schematically shown in Figure A2.

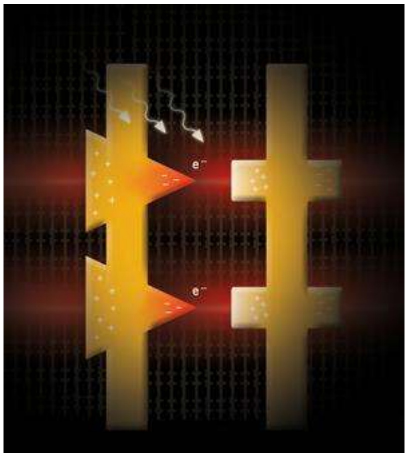
New patented fabrication technique key to new solar power technology

February 27, 2013 by Colin Poitras



This is an illustration of a working optical rectifying antenna, or rectenna. Credit: (Illustration by Justine Braisted/UConn)

A novel fabrication technique developed by a University of Connecticut engineering professor could provide the breakthrough technology scientists have been looking for to vastly improve the efficiency of today's solar energy systems.

For years, scientists have studied the potential benefits of a new branch of solar energy technology that relies on nanosized antenna arrays theoretically capable of harvesting more than 70 percent of the sun's electromagnetic radiation and simultaneously converting it into usable electric power.

But while nanosized antennas that also serve as rectifiers have shown promise in theory, scientists have lacked the technology required to construct and test them. The fabrication process is immensely challenging. The nano-antennas – known as "rectennas" because of their ability to both absorb and rectify solar energy from alternating current to direct current – must be capable of operating at the speed of visible light and be built in such a way that their core pair of electrodes is a mere 1 or 2 nanometers apart, a distance of approximately one millionth of a millimeter, or 30,000 times smaller than the diameter of human hair.

The potential breakthrough lies in a novel fabrication process called selective area atomic layer deposition (ALD) that was developed by Brian Willis, an associate professor of chemical and biomolecular engineering at the University of Connecticut and the former director of UConn's Chemical Engineering Program.

It is through atomic layer deposition that scientists believe they can finally fabricate a working rectenna device. In a rectenna device, one of the two interior electrodes must have a sharp tip, similar to the point of a triangle. The secret is getting the tip of that electrode within one or two nanometers of the opposite electrode, something similar to holding the point of a needle to the

plane of a wall. Before the advent of ALD, existing lithographic fabrication techniques had been unable to create such a small space within a working electrical diode. Using sophisticated electronic equipment such as electron guns, the closest scientists could get was about 10 times the required separation. Through atomic layer deposition, Willis has shown he is able to precisely coat the tip of the rectenna with layers of individual copper atoms until a gap of about 1.5 nanometers is achieved. The process is self-limiting and stops at 1.5 nanometer separation.

The size of the gap is critical because it creates an ultra-fast tunnel junction between the rectenna's two electrodes, allowing a maximum transfer of electricity. The nanosized gap gives energized electrons on the rectenna just enough time to tunnel to the opposite electrode before their electrical current reverses and they try to go back. The triangular tip of the rectenna makes it hard for the electrons to reverse direction, thus capturing the energy and rectifying it to a unidirectional current.

Brian Willis holds a rectenna device. Credit: Sean Flynn/UConn Photo

Impressively, the rectennas, because of their extremely small and fast tunnel diodes, are capable of converting solar radiation in the infrared region through the extremely fast and short wavelengths of visible light – something that has never been accomplished before. Silicon solar panels, by comparison, have a single band gap which, loosely speaking, allows the panel to convert electromagnetic radiation efficiently at only one small portion of the solar spectrum. The rectenna devices don't rely on a band gap and may be tuned to harvest light over the whole solar spectrum, creating maximum efficiency.

Willis and a team of scientists from Penn State Altoona along with SciTech Associates Holdings Inc., a private research and development company based in State College, Pa., recently received a $650,000, three-year grant from the National Science Foundation to fabricate rectennas and search for ways to maximize their performance.

"This new technology could get us over the hump and make solar energy cost-competitive with fossil fuels," says Willis. "This is brand new technology, a whole new train of thought."

The Penn State Altoona research team – which has been exploring the theoretical side of rectennas for more than a decade – is led by physics professor Darin Zimmerman, with fellow physics professors Gary Weisel and Brock Weiss serving as co-investigators. The collaboration also includes Penn State emeritus physics professors Paul Cutler and Nicholas Miskovsky, who are principal members of Scitech Associates.

"The solar power conversion device under development by this collaboration of two universities and an industry subcontractor has the potential to revolutionize green solar power technology by increasing efficiencies, reducing costs, and providing new economic opportunities," Zimmerman says.

"Until the advent of selective atomic layer deposition (ALD), it has not been possible to fabricate practical and reproducible rectenna arrays that can harness solar energy from the infrared through the visible," says Zimmerman. "ALD is a vitally important processing step, making the creation of these devices possible. Ultimately, the fabrication, characterization, and modeling of the proposed rectenna arrays will lead to increased understanding of the physical processes underlying these devices, with the promise of greatly increasing the efficiency of solar power conversion technology."

The atomic layer deposition process is favored by science and industry because it is simple, easily reproducible, and scalable for mass production. Willis says the chemical process is particularly applicable for precise, homogenous coatings for nanostructures, nanowires, nanotubes, and for use in the next generation of high-performing semi-conductors and transistors.

The method being used to fabricate rectennas also can be applied to other areas, including enhancing current photovoltaics (the conversion of photo energy to electrical energy), thermoelectrics, infrared sensing and imaging, and chemical sensors.

Over the next year, Willis and his collaborators in Pennsylvania plan to build prototype rectennas and begin testing their efficiency.

"To capture the visible light frequencies, the rectenna have to get smaller than anything we've ever made before, so we're really pushing the limits of what we can do," says Willis. "And the tunnel junctions have to operate at the speed of visible light, so we're pushing down to these really high speeds to the point where the question becomes 'Can these devices really function at this level?' Theoretically we know it is possible, but we won't know for sure until we make and test this device."

Abstract

Wireless power transmission was conceptualized nearly a century ago. Certain achievements made to date have made power harvesting a reality, capable of providing alternative sources of energy. This review provides a summ ary of radio frequency (RF) power harvesting technologies in order to serve as a guide for the design of RF energy harvesting units. Since energy harvesting circuits are designed to operate with relatively small voltages and currents, they rely on state-of-the-art electrical technology for obtaining high efficiency. Thus, comprehensive analysis and discussions of various designs and their tradeoffs are included. Finally, recent applications of RF power harvesting are outlined.

Background

Motivation for wireless energy harvesting

An early definition of a wireless power transmission system portrays a unit that emits electrical power from one place and captures it at another place in the Earth's atmosphere without the use of wires or any other supporting medium [1]. The history of RF power scavenging in free space originated in the late 1950s with a microwave-powered helicopter system [2]. Later, the concept of power harvesting or energy scavenging was explained as a technique for reaping energy from the external environment using different methods including thermoelectric conversion, vibrational excitation, solar energy conversion, and pressure gradients. This technique promises tremendous scope for the replacement of small batteries in low power electrical devices and systems. Figure 1 introduces the structure of an RF energy harvesting system and factors that contribute to the performance of the whole system.

Fig. 1

Conceptual block diagram of an RF power harvesting system

RF wireless power harvesting (WPH) holds vast potential for replacing batteries or increasing their lifespans. Currently, batteries power a majority of low-power remote sensor devices and embedded equipment. In fact, batteries have finite lifespans and require periodic replacements. By applying power harvesting technologies, devices and equipment can become self-sustaining with respect to the energy required for operation, thereby obtaining an unlimited operating lifespan. Thus, the demand for power maintenance will become negligible.

The sources for WPH are available in many forms, such as solar power [3, 4, 5], wind energy [6, 7, 8], thermal energy [9, 10, 11], electromagnetic energy [12, 13, 14], kinetic energy [15, 16, 17], etc. Among them, electromagnetic energy is abundant in space and can be retrieved without limit. Electromagnetic waves come from a variety of sources such as satellite stations, wireless internet, radio stations, and digital multimedia broadcasting. A radio frequency power harvesting system can capture and convert electromagnetic energy into a usable direct current (DC) voltage. The key units of an RF power harvesting system are the antenna and rectifier circuit that allows the RF power or alternating current (AC) to be converted into DC energy.

The processing of battery wastes is a critical problem. A majority of batteries end up in landfills, leading to the pollution of the land and water underneath. The most effective solution for reducing battery wastes is to avoid using them. Applying WPH technology will help to reduce the dependency on batteries, which will ultimately have a positive impact on the environment. Moreover, the process of harnessing electromagnetic energy will not generate wastes as it is a clean energy source.

A summary of the present sources of energy available for power harvesting is shown in Table 1. The data in Table 1 was collected from references [18, 19]. In comparison with thermal or kinetic energy, electromagnetic energy is not limited by space or time. The RF wave is available both indoors and outdoors, in rural and urban areas, throughout the day. Despite its low power density in the environment, an intentional source can be added for more efficient power transmission and a boosting circuit can be built to suit the requirements of the load application. This feature promotes research to realize RF WPH technology through applications such as wireless sensor networks (WSNs) and Internet of Things (IoT).

Table 1

Overview of alternative sources of energy to replace batteries

Source	**Power density**	**Harvesting tech.**	**Advantages**	**Disadvantages**
Solar	Indoor: 10 μW/cm^2 Outdoor: 10 mW/cm^2	Photovoltaic	High power density Mature	Not always available Required exposure to light (not implantable) Expensive
Vibration	Human: 4 μW/cm^2 Industrial: 100 μW/cm^2	Piezoelectric Electrostatic Electromagnetic	Implantable High efficiency	Not always available Material physical limitation
Thermal	Human: 30 μW/cm^2 Industrial: 1–10 mW/cm^2	Thermoelectric Pyroelectric	High power density Implantable	Not always available Excess heat
RF	GSM: 0.1 μW/cm^2 WI-FI: 1 mW/cm^2	Antenna	Always available Implantable	Low density Efficiency inversely proportional to distance

Fundamentals of RF transmission

Understanding electromagnetic waves is important to design an RF WPH system. The behavior of electromagnetic waves varies according to the distance, frequency, and conducting environment. Depending on the requirements of the application, the designer needs to select suitable parameters for electromagnetic waves to obtain best results.

The loss of power in space can be characterized by free space path loss (FSPL), which is the loss of signal power during propagation in free space. Calculating FSPL requires information about the antenna gain, frequency of transmitting wave, and distance between the transmitter and receiver.

The behavior of electromagnetic waves depends upon the distance from the transmitting antenna. These characteristics are categorized into two segments: far-field and near-field [20]. While the electromagnetic wave pattern at the far-field is relatively uniform, in the near-field, the electric and magnetic components are very strong and independent such that one component can dominate the other. The near-field region is considered as the space that lies within the Fraunhofer's distance and the far-field region lies outside the Fraunhofer's distance. The distribution of the near and far field regions is illustrated in Fig. 2. The Fraunhofer's distance is defined as

$$d_f = \frac{2D^2}{\lambda},$$

(1)

where d_f is the Fraunhofer's distance, D is the maximum dimension of the radiator (or diameter of the antenna), and λ is the wavelength of the electromagnetic wave. Although the Fraunhofer creates a boundary region, the actual transition between regions is not distinct. Inside the near-field, the space from the antenna to a distance of $\sqrt[3]{\frac{D}{2\lambda}}$ is a non-radiative/reactive near-field region, where E and H fields are not in phase, creating energy distortion. As we propagate forward in this region towards the far-field, we encounter a radiative near-field or Fresnel region, where the reactive behavior of electromagnetic waves is not dominant but the phases of E and H fields still vary with distance.

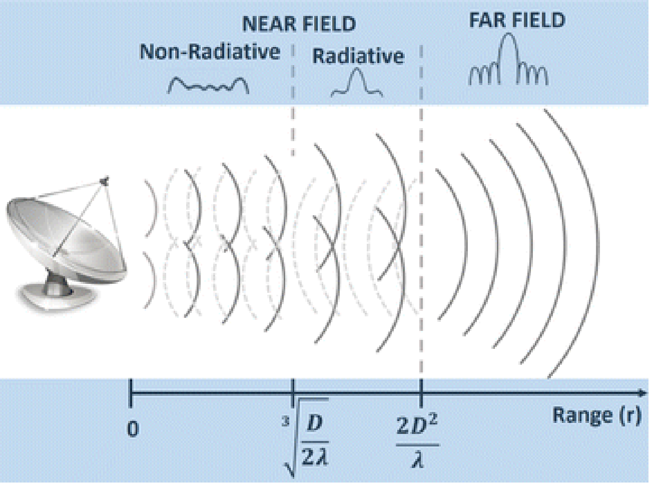

Fig. 2

Distribution of near field and far field regions in space

For a transmitter–receiver antenna in the far-field free space, the power propagation at the receiver antenna can be expressed as

$$P_R = \frac{P_T G_T G_R \lambda^2}{(4\pi R)^2},$$

(2)

where P_R is power at the receiver antenna; G_R is receiver antenna gain relative to the isotropic source (dBi); λ is the wavelength of the electromagnetic signal, which is equal to the speed of light in vacuum divided by the signal frequency, $\lambda = \frac{c}{f}$; and $k = 2\pi/\lambda$ is the wave number. From the above formula, the FSPL, P_L for far-field can be inferred as

$$P_L = \frac{P_T}{P_R} = \frac{(4\pi R)^2}{G_T G_R \lambda^2} = \frac{(4\pi f R)^2}{G_T G_R c^2} = \frac{4}{G_T G_R}(kR)^2$$

(3)

or

$$P_L\,(dB) = 20\log_{10}(f) + 20\log_{10}(R) + 20\log_{10}\left(\frac{4\pi}{c}\right) - G_T - G_R$$

(4)

In case f is measured in MHz, distance R is measured in km, and gain G_T and G_R are measured in dBi, the above function becomes

$$P_L\,(dB) = 20\log_{10}(f) + 20\log_{10}(R) + 32.44 - G_T - G_R$$
(5)

By using the path loss equation, it is possible to indicate the signal power at the far field region. However, this equation does not present all the factors that affect the propagation process such as reflection, diffraction, absorption, etc.

In contrast to the uniform far-field wave, the electric and magnetic fields behave unusually in the near-field. The relationship between electric and magnetic waves in the near-field varies unpredictably with time and space and is too complicated to predict. All these factors make estimating the power density at this range problematic.

The FSPL estimation process is critical to design the energy-harvesting unit. Being informed about the amount of power that the system is required to handle helps the designer in choosing the right technology and method.

Since the electromagnetic field (EMF) is widely used for a variety of purposes, there must be a standard to ensure the safe operation of EMF devices. For this purpose, the International Electrotechnical Commission [21] established international standards and frequency limits for EMFs. For safety measures, there must be a separate emission and immunity standard for each class of application including broadcast, communication, military, medical, and household appliances.

On the other hand, radiation exposure must be considered carefully, especially in biomedical applications. EMFs at different spectrums affect the human body differently. Between 1 MHz to 10 GHz frequency, EMF possibly penetrates through tissues and produce heat because of energy absorption. EMFs over 10 GHz are strongly blocked by the skin, and then the heat created causes damage such as eye cataracts or skin burns if the field density is above 1000 W/m^2. Hoping to prevent negative health effects when utilizing EMF applications, the International Commission on Non-Ionizing Radiation Protection (ICNIRP) developed general guidelines for EMF exposure limits recognized under the World Health Organization (WHO). To date, there have been no consistent reports corroborating that lasting exposure to EMF shortens one's life span or induces adverse health conditions. However, for safety issues, RF emission power and frequency must be considered carefully to avoid unwanted damages.

Wireless power harvesting evaluation metrics

There are various parameters that need to be evaluated, which decide the performance of a WPH design. Evaluation merits change depending on different applications. Nevertheless, critical values such as efficiency, sensitivity, operation distance, output power are defined as standards to make comparisons. However, tradeoffs exist between these values such as operation distance and overall efficiency. Moreover, besides this merit, other manufacturing auxiliary factors like low cost, maturity of fabrication process, and bulk manufacturing availability are also paramount.

Operation range

Operation distance is mostly related to operation frequency. In fact, transmission at high frequencies is attenuated by atmospheric conditions more than at low frequencies while low frequency penetrates deeper through matter. Therefore, if the application of WPH is for implantable devices, then the transmitting frequency should not exceed the megahertz range.

RF-DC power conversion efficiency (PCE)

This is the ratio between the amount of power applied to the load and that retrieved by the antenna. Generally, the RF-DC PCE covers the efficiency of the rectifier, voltage multiplier, and storage elements. PCE can be simply calculated as the ratio of power delivered to the load to the retrieved power. RF transmission loss in space is not considered in this term.

$$\eta_{PCE} = \frac{P_{load}}{P_{retrived}},$$
(6)

where P_{load} is power delivered to the load and $P_{retrieved}$ is harvested power at the antenna. Factors that determine the value of PCE include parasitic effects, leakage in the circuits, design topologies, and nonlinear thresholds of electrical components.

Resonator Q factor

The Q factor is generally defined as a dimensionless value that describes how strong the resonance is and the bandwidth of resonance [22]. In electric circuits, the Q factor represents how much the peak voltage increases when the system resonates at resonant frequency. From this concept, the equation of Q factor can be express as the formula below [23]:

$$Q = 2\pi \frac{Energy\, stored}{Energy\, dissipated\, per\, cycle}\, or\; Q = \frac{f_c}{\Delta f}$$

(7)

From the equation above, it is inferred that a high Q factor comes with a narrow resonant bandwidth, but high voltage gain is obtained at resonance. Further, this equation also indicates that the Q factor is inversely proportional to the energy dissipated per cycle. The specific Q factor for capacitor C and inductor L at frequency ω is given by

$$\text{Capacitor Q factor:}\, Q_C = \frac{1}{\omega R_c C} = \frac{X_c}{R_c},$$

(8)

$$\text{Inductor Q factor:}\, Q_L = \frac{\omega L}{R_L} = \frac{X_L}{R_L},$$

(9)

where R_C is the series resistance of capacitor and R_L is the series resistance of inductor. From the equations of Q_C and Q_L, we note that resistive component is the cause of power dissipation. Additionally, in an electrical circuit, energy loss can be reduced by adding reactive components such as capacitors or inductors and minimizing resistive components. Since obtaining a high Q factor is a usual consideration in designing WPH systems, this feature is typically included in the impedance matching network design.

Sensitivity

Sensitivity of a WPH system is defined as the minimum limit of incident power that is required to trigger the operation of the system. Sensitivity is quantified as follows:

$$Sensitivity\ (dBm) = 10 \log_{10}\left(\frac{P}{1mW}\right),$$

(10)

where P is the minimum power the system requires to perform a task.

The threshold voltage of CMOS technology affects sensitivity. A lower threshold CMOS is more sensitive but comes with more leakage current, which reduces the overall efficiency.

Output power

Usually, the outcome of a WPH system is DC power, which is characterized by load voltage V_{DD} and current I_{DD}. Measuring open-load voltage demonstrates the performance of WPH in general since V_{DD} and I_{DD} depend on load impedance. If the load is a sensor, V_{DD} is more important than I_{DD} while in applications like electrolysis or LED, current is the dominant parameter.

Recent advances in wireless power harvesting

Antenna/rectenna design

Gain, resonance frequency, bandwidth are parameters that characterize the performance of an antenna. Assuming an unobstructed space and isotropic transmitting source, the spreading of the waves in all directions is uniform. Thus, the power per unit area at a distance from the source is inversely proportional to the square of the distance:

$$S_{isotropic} = \frac{P_T}{4\pi R^2},$$

(11)

where R is the distance from the source, S is power per unit area at the distance R, and P_T is the transmitted power. However, it is important to note that antennas do not always transmit power spherically (isotropic antenna), they also transmit energy in some specific directions according to their designs. The ratio between the maximum power density of an antenna at a given distance to the power density of an optimal omnidirectional or isotropic antenna at the same distance, radiating the same power, is known as antenna gain (G). This parameter represents the directivity of an antenna. Since power density (S) is non-directional, the definition of S was developed as a function of direction i.e. S (θ, φ). Consequently, the gain of the antenna is a directional function as well. It is defined as the ratio of the antenna's power density in a given direction to the power density of an isotropic antenna as formula below

$$G\left(\theta,\varphi\right)=\frac{\mathrm{S}\left(\theta,\varphi\right)}{S_{isotropic}}=\frac{4\pi R^2 S\left(\theta,\varphi\right)}{\mathrm{P}_t},$$

(12)

Thus, the power density at a distance R from an antenna in general is given by

$$S=\frac{P_T G_T}{4\pi R^2},$$

(13)

where P_T is the transmitted power by the antenna and G_T is the transmitting antenna gain. It is known that an ideal isotropic antenna has $G_T = 0$ dBi. The aforementioned formula is also applicable to receiving antennas. Specifically, for power harvesting applications, a receiving antenna, which constitutes a rectifier, is called a rectenna.

Preference for a high gain antenna depends on the application requirements. In case of RF transmission, if the positions of source and receiving antennas are known, then a high gain rectenna is advantageous. On the other hand, if the positions of the source and receiving antenna are relatively uncertain, a low gain antenna is preferable in order to collect signals from various directions simultaneously.

Every antenna has its own optimal operation frequency known as resonance frequency (Fig. 3). The resonance frequency is determined by the capacitance and inductance characteristics of the antenna. As frequency increases, inductive behavior becomes dominant and capacitance decreases. The frequency at which the inductance and capacitance nullify each other, minimizing the impedance of the antenna, is called the resonance frequency.

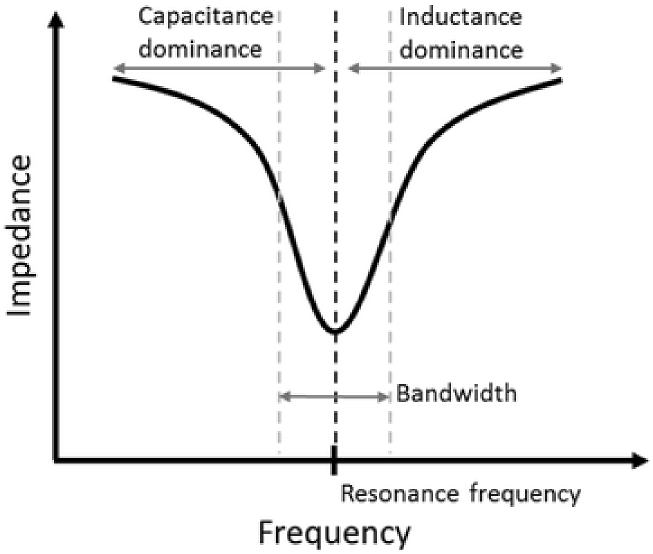

Fig. 3

Correlation between impedance and resonance frequency, and bandwidth of an antenna

The capacitance and inductance are functions of the frequency and physical size of the antenna. The larger the dimensions of the antenna, the lower the resonance frequency. Therefore, transmitting and receiving low frequency waves requires a large aperture, which is not suitable for small device applications. The antenna designed in [24] has a sensitivity as low as −35 dBm (0.32 µW), but the tradeoff is a large size aperture measuring up to 64.68 cm^3 (7 × 7 × 1.32 cm).

The bandwidth of an antenna is the range of frequencies in which the antenna can operate efficiently. A wide bandwidth antenna can collect signals from a wider range of frequencies than a narrow bandwidth antenna. Hence, a wide bandwidth antenna is advantageous in retrieving incident energy but presents a high risk of interference by noise through unwanted frequencies (Table 2).

Communication antennas have been studied for decades. However, power-harvesting antennas are currently in the developmental stage. At first, antenna classification was based on design characteristics and applications. It originally included wire antennas, aperture antennas, printed planar antennas, and reflector antennas. An illustration of some examples of antennas is shown in Fig. 4. To date, the growth in technology has paved the way for a variety of antenna design and fabrication methods for making it more compact and mature.

The plate antennas are popular and have many applications [27, 34, 38]; on-chip antennas are preferred for small and compact applications. Recently, many publications addressed wide-band and multi-band antennas. It has been proven that narrow-band antennas offer high energy conversion efficiencies but can only retrieve a limited amount of energy. On the other hand, wide-band or multi-band frequency antennas can retrieve more RF energy in space. However, the tradeoffs are low overall efficiency and large aperture. In [32], antennas with a resonance frequency of 4.9 and 5.9 GHz were designed with PCEs of 65.2 and 64.8%, respectively. Further work by Lu et al. [26] on polarization antennas supports the assertion that expanding the bandwidth of an antenna leads to increasing the amount of power harvested. In this work, the demonstration of broadband polarization antennas with three separate modes allows the antenna to operate in a wider range of frequencies. One common mechanism in the aforementioned works is the control of the antenna configuration by switching the diodes on and off, thus altering its resonant frequencies. However, since it uses separate modes for different frequencies, this antenna is not able to simultaneously resonate at two frequencies. On the other hand, the antenna presented in [39] is capable of operating at 2.45 and 5.8 GHz, simultaneously, providing 2.6 V output with a PCE of 65% and power density of 10 mW/cm^2.

The main purpose of aligning antennas in arrays is to enhance the antenna gain and obtain high voltage/current. Array antennas are preferred over large aperture antennas because they do not require large breakdown voltage diodes to operate. Antenna arrays can be connected before or after rectification. The first configuration enhances the retrieved power at the main beam while the second configuration expands the ability to retrieve power from various angles away from the main beam [40]. In case the RF waves are combined before rectification, the rectifier requires a large breakdown diode. If RF waves are combined after rectification, combining DC current becomes problematic. Antenna arrays can be connected in series or parallel to obtain high voltage or large current. Nonetheless, expanding the arrays yields better output but this might cause a deduction in conversion efficiency [33].

For demonstrating antenna arrays, Sun et al. [35] invented a T-junction to connect four quasi-Yagi antennas together. The advancement in this work was that the T-junction was flexible in changing from 1 × 4 array to 2 × 2 array topologies. Consequently, the system was able to operate at an ambient power level as low as 455 µW/cm^2 while obtaining 40% PCE.

Impedance matching network

In low-power consumption electrical systems, power leakage during transmission may lead to energy insufficiency. In these circumstances, adding an impedance matching network (IMN) ensures that the maximum power transfers between the RF source and load. For WPH applications, the receiving antenna is considered as the source while the rectifier/voltage multiplier is considered as the load. It is acknowledged that in DC, power transfer is optimum when the resistances of the source and load are indistinguishable. In an RF circuit, the impedance is referred to instead of resistance. An impedance mismatch between the source and load creates reflected power flow in the circuit that lowers the efficiency of the system. As its name indicates, the IMN ensures that the impedance of the source and load are identical by adding reactive components in between.

There are three basics matching configurations i.e. L, T and π matching networks (Fig. 5). The L matching is commonly used since it typically has two components, which simplifies the designing and controlling process. Additionally, the L matching networks do not alter the quality factor (Q) of the circuit.

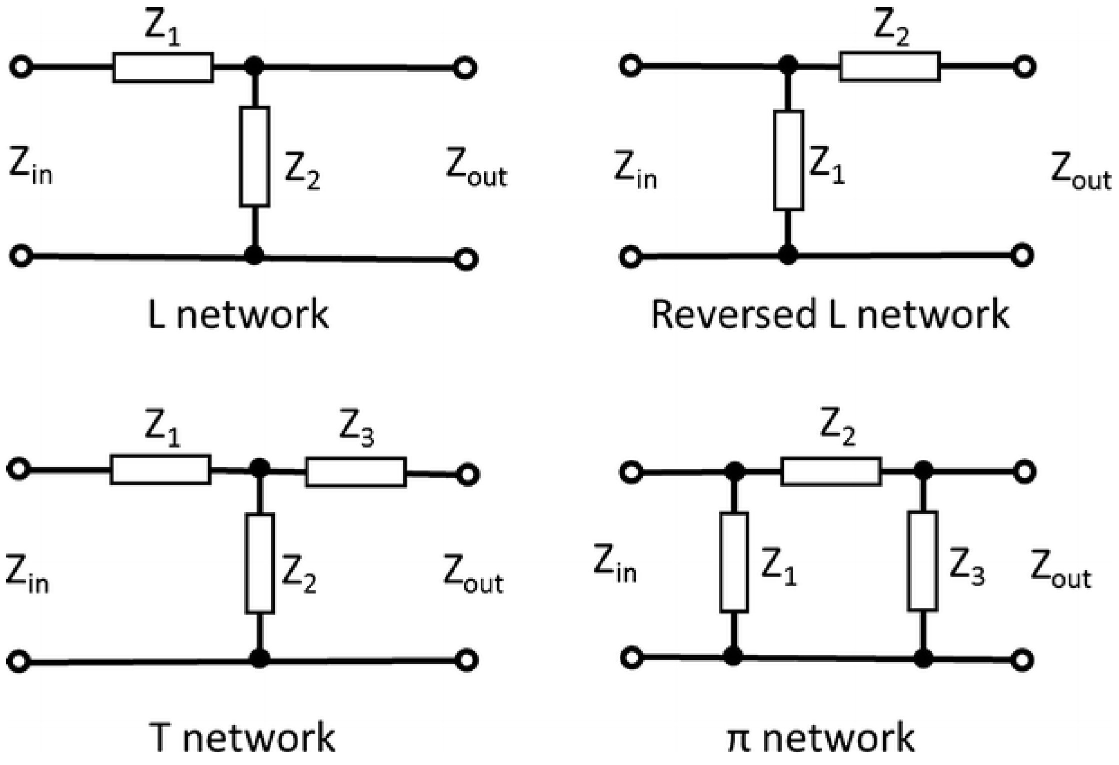

Fig. 5

Configuration of common impedance matching networks

The T and π matching configurations are more complex than the L network. Furthermore, organizing the T and π configurations into multiple stages will retain the final matching results but will change the Q factor. This strategy is useful in improving voltage boost.

There are tradeoffs between the attributes of an IMN, which include frequency, bandwidth, adjustability, and complexity. For instant, in [41], the suboptimal impedance matching and multiport ladder matching methods were introduced to enhance the matching performance and harvested power of antennas, respectively. However, the tradeoff was that implementation of these configurations required more components than traditional matching networks, thus, escalating the circuit's complexity.

Etor et al. [42] designed an IMN for THz frequencies applications using transmission lines and self-designed metal–insulator-metal diodes instead of lumped components. Moreover, fixed IMN and tunable IMN [43, 44, 45] were introduced as a technique for better matching with wide-band and multi-band antennas.

Rectifier/voltage multiplier

RF energy extracted from free space usually possesses low power density since the electric field power density decreases at the rate of $1/d^2$, where d is the distance from the RF source [46]. Therefore, a power amplifier circuit is required that yields enough DC energy from the electromagnetic waves to drive the loads. This gives rise to two possibilities, if the power consumption of the load is lower than the average power harvesting, the electronic devices at the load may work continuously; otherwise, if the load consumes more energy than the power harvesting circuit can generate, the devices cannot work continuously [47].

Rectifying is the most popular application of diodes, which refers to the conversion of AC current to DC current. In terms of power harvesting application, the RF signal retrieved in the antenna has a sinusoidal waveform. The signal after transformation through IMN would be rectified and boosted to meet the power requirements of the application.

The most fundamental topology of the rectifier is the half-wave rectifier that comprises of a single diode D1 (Fig. 6a). When AC voltage transfers through D1, only the positive cycle remains and the negative cycle is cutoff; thus, it diminishes half of the AC power. Moreover, the output V_{out} is discontinuous since the negative cycle is cutoff. Despite its simplicity, a half-wave rectifier is usually inadequate for common applications. Hence, a full-wave rectifier is more preferable. The circuit design of the full-wave rectifier is shown in Fig. 6b. During the first negative cycle of AC input, diode D1 is conductive and capacitor C1 is charged to the corresponding energy level of V_{peak} of the input. Then, at the next positive cycle, diode D1 is blocked, diode D2 is conductive so that capacitor C2 is also charged. In consequence, the output V_{out} would see two capacitors in series (each one is storing a voltage of $V_{peak)}$. Thus, V_{out} is twice V_{peak}. Therefore, this topology is more stable and efficient than the half-wave rectifier. There is also a bridge rectifier that rectifies both positive and negative cycles of the AC input but retains $V_{out} = V_{peak}$ by alternatively blocking pairs of diodes D1, D4 and D2, D3 (Fig. 6c).

Fig. 6

Some common topologies of a rectifier

Voltage multiplier is a special type of rectifier circuit that converts and boosts AC input to DC output. In some case where the rectified power is inadequate for the application, there is a need for boosting the output DC by stacking single rectifiers into series, forming the voltage multiplier [48]. Several configurations of the voltage multiplier are shown in Fig. 7. The most fundamental configuration is the Cockcroft–Walton voltage multiplier (Fig. 7a). This circuit's operational principle is similar to the full-wave rectifier (Fig. 6b) but has more stages for higher voltage gain. The Dickson multiplier in Fig. 7b is a modification of Cockcroft–Walton's configuration with stage capacitors being shunted to reduce parasitic effects. Thus, the Dickson multiplier is preferable for small voltage applications. However, it is challenging to obtain high PCE due to the high threshold voltage among diodes creating leakage current, thus reducing the overall efficiency. Additionally, for high resistance loads, output voltage drops drastically leading to low current supply to the load. A summary of recent works related to voltage multiplier is shown in Table 3.

The MOSFET (metal–oxide–semiconductor field effect transistor) technology is overcoming the limitations of diodes and becoming an alternate solution for rectifying and boosting. Owing to MOSFET technology, Dickson multiplier can be integrated together in integrate circuits (IC) by replacing diodes with NMOS as shown in Fig. 7c. Relatively low threshold voltages and high PCEs are features of this design. Moreover, differential drive voltage multiplier (Fig. 7d) is widely used because of its low leakage current and potential for further modification for specific applications. A detail explanation and analysis is presented in [49, 50].

There is a strong relationship between the number of stages of a voltage multiplier and its sensitivity and efficiency. As the number of stages increase, there is more loss across each added stage. However, the tradeoff is higher voltage multiplication and small threshold voltage at the first stage. On the other hand, a voltage multiplier with a few stages has less voltage drop between its stages but requires higher threshold voltage for all stages to work simultaneously. For this reason, a voltage multiplier becomes more sensitive when a large number of stages are present and becomes more efficient at fewer stages. This tradeoff feature was analyzed in several researches [53, 58]. Therefore, the optimal number of stages should be considered depending upon the application targets.

Pros and cons of Schottky diode and CMOS technology

Rectifying elements such as diodes or transistors are indispensable components of the rectifier/voltage multiplier block, which determine operation frequency and power-conversion efficiency. Traditionally, a Schottky diode was used because of its low threshold voltage. Moreover, there are also Esaki (tunnel) diodes, metal–insulator–metal (MIM) diodes, and spin diodes with recent technology enhancements that make it more mature. Particularly, the Esaki diode can operate at very high frequency with fast response because of its low parasitic elements. Moreover, the MIM diodes technology makes integration with CMOS process possible, which is a limitation of Schottky diodes. Spin diodes offer lower threshold voltages than Schottky diodes.

There are several parameters that need to be considered when choosing a diode for designing a voltage multiplier. These include RF to DC power conversion efficiency, parasitic efficiency, and matching efficiency. When it comes to microwatt applications, Schottky diodes face some limitation in RF-DC conversion efficiency because of their high zero-bias junction resistance [59]. However, owing to recent developments in technology, if the retrieved power is less than −30 dBm (1 µW), then the low-barrier SMS7630 and VDI W-Band ZBD diodes are recommended due to their low parasitic power losses and low power dissipation in the matching network [60].

Recently, many publications have moved toward CMOS processes, since they not only assist in custom designing in electronics but are also more sensitive to low operation voltages than traditional Schottky diodes. Many researches focus on modifying present rectifier and voltage multiplier topologies to achieve higher gain, sensitivity, efficiency [52, 55, 56, 57, 61]. For instance, the voltage multiplier achieved maximum 11% PCE at −24 dBm (4 µW) in [62] and 41% PCE at −20.6 dBm (8.7 µW) input power in [57]. While the majority of publications utilized 0.18 µm CMOS technology in their work, [52] applied commercial 40 nm CMOS process to build a low-voltage operation voltage multiplier that reached 44% PCE at 390 mV input. Hwang et al. [54] applied reducing reverse loss to minimize the reverse leakage loss in the rectifier, thus increasing the overall efficiency.

Similar to Schottky diodes, the number of stages directly dictates the performance efficiency in the task of designing a custom CMOS voltage multiplier. A basic assumption when using transistors is that the retrieved RF signal from the antenna must be high enough to trigger the transistors on and off. Different voltage multiplier topologies possess different features and characteristics. However, as long as transistors are used in the design, there is considerable amount of voltage drop among transistors. It has been observed that the major cause of rectified voltage drop is the threshold loss. If the number of stages increases, the threshold voltage at the transistors also adds up, requiring the higher amplitude RF signal to trigger the transistors [62]. Therefore, the number of stages in the majority of publications usually does not exceed 10.

Designing and optimizing the WPH system

The efficiencies of individual modules and the integration of all modules together constitute the total efficiency of a WPH system. As a consequence, the only way to optimize the total efficiency is to maximize efficiencies of each module and consolidate them in harmony. Commonly, several tests and adjustments need to be done to obtain an optimized WPH system. The work flow of designing a WPH system is described in Fig. 8.

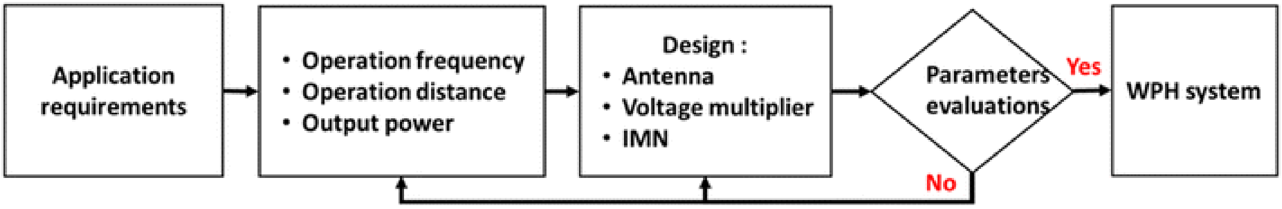

Fig. 8

WPH system's designing protocol

Firstly, choosing the appropriate operation frequency to the application's requirement critically dictates the efficiency of the WPH system. Secondly, the operation range also need to be specified. Long range (far-field) power harvesting or transmission requires high frequency such as 2.45, 5.24 GHz, whereas short range (near-field) applications requires electromagnetic waves at frequencies in the megahertz range. Additionally, for power harvesting in dense environment different from air, very low frequency (~kHz) is preferable. Besides the operation frequency and distance, the required output power and voltage determines the suitable topology of the voltage multiplier.

Based on the operation and application, the antenna's design has to match the gain, frequency and size. Choosing the right rectifying element is also critical. For rectifier and voltage multiplier modules in general, the dependence of RF-DC PCE on frequency and output load was discussed in [50]. In addition, it is obligated to have a correct-tuned IMN for maximum power transfer inside the WPH circuit.

Detailed features of individual modules of the WPH system are explained and discussed in the previous sections. The problem of optimizing the WPH system becomes the game of defining the goals and integrating individual modules in harmony to archive the goal.

Applications

RF power harvesting in medical and healthcare

In order to deploy WPH in the real world, power consumption rate of the device should be less than the harvested power. Since retrieved power is unstable and difficult to predict, an energy storage module is highly recommended to enhance its consistency. If the WPH is integrated to the device as a single system on chip, the total size of the system would be reduced significantly.

The first wireless battery-free bio-signal processing system on chip [63] was introduced by [64]. This system was able to monitor various bio-signals via electrocardiogram (ECG), electromyogram (EMG), and electroencephalogram (EEG). The total size of the chip was 8.25 mm^2. This chip only consumed 19 µW to measure heart rate. The power module of this system comprised an RF WPH that was supported by a thermoelectric generator, which together supplied a voltage of 1.35 V. Table 4 presents the performance of several health monitoring system on chips (SoCs). The majority of chips have the advantages of small size, low voltage supply and low power consumption which is applicable to be integrated with WPH technology.

Table 4

Power consumption of published SoC devices

Ref.	Sensors	Operation voltage (V)	Chip power (µW)	Size (mm)
[21]	Intraocular pressure (IOP)	–	0.0053	0.5 × 1.5 × 2.5
[65]	ECG, Bio-impedance	1.2	345–374	7 × 7

Ref.	Sensors	Operation voltage (V)	Chip power (µW)	Size (mm)
[66]	ECG	1.2	32	5 × 4.7
[64]	ECG, EMG, EEG	1.2	19	2.5 × 3.3
[67]	ECG, thoracic impedance variance (TIV)	1.2	2400	5 × 5
[68]	EEG	1	77.1	2.5 × 2.5
[69]	Temperature, pressure	0.4/0.5	7.7	2.2 × 2.7
[70]	Neural, ECG, EMG, EEG	1	500	2.5 × 1

It is a fact that a considerable amount of TV broadcast signals never reach the TV. Fortunately, WPH technology can harness this wasted energy without causing any effect on the TV broadcasting quality. In this context, Nishimoto et al. [71] have explored this potential source of energy to remove batteries from temperature monitoring WSNs. Since the power density of TV broadcasts is relatively weak, an array antenna was designed to collect multi-frequency waves. Compared to the antenna array designed in [72], the antenna rectifying efficiency obtained was higher by 50% in the frequencies between 15 and 800 MHz. This design is reported to successfully measure and transmit data every 5 s.

In some research experiments where free movement is unavoidable, stimulation signal and response data has to be delivered and collected wirelessly. In these circumstances, RF WPH is a superior choice in comparison with inductive coupling transmission technology to power the wireless system. Cobo et al. designed an implantable micro-pump that is powered by inductive coupling coils. Even though this work has obtained high efficiency power transmission, the operation range is limited to a few centimeters from the source. On the other hand, in [73], the RF electromagnetic waves were deployed to power optogenetic microneedles to be wirelessly injected into mice. The design of WPH in this work was able to retrieve 4.08 mW power at a distance of 1 m from the 7.9 W source at a frequency of 910 MHz. Another rectenna was built for mounting on the mice’ heads for deep brain stimulation (DBS) devices [31]. In this system, the power-harvesting module retrieves 0.254 mW DC power at a maximum operation distance of 20 cm. With this available power, the DBS device generates 200 µA pulses at 130 Hz. The above results show that RF WPH technology offers a better operation range than traditional inductive coupling power transmission technology. It is now possible to harvest sufficient power to run low-power consumption devices in the range of meters. The noninvasive bio-telemetry system for monitoring and investigating various health indexes is a promising field for WPH technology. Cheng et al. [74] introduced a power harvesting design that included a loop antenna to be attached to the pig eye with 31% PCE and output power up to 2.10 mW. Additionally, in vivo experiments, using WPH technology to supply medical devices for implantation in rapid eyes was demonstrated without recorded side effects [63, 75].

Wireless power harvesting network (IoT/WSN)

Along with the development of the micro-electro-mechanical systems (MEMS) technology, wireless sensor networks have gained widespread popularity in recent years. This field has achieved several milestones and is still developing further. WSNs applications widespread from smart house, healthcare to industry and military. In addition to the issues of sensing reliability, communication protocol, and network services, energy is a critical concern in WSNs [76]. Sensor nodes of WSNs are low power devices, and minimization of energy consumption and application of WPH to replenish power storage elements are two concurrent schemes to maximize the network lifespan. Recently, several researches were done to find optimized approaches to power WSNs including RF power harvesting [77, 78, 79, 80, 81].

Energy is the greatest challenge in deploying WSNs [82]. Applying RF energy to recharge the batteries is one approach to enhance the lifespan of WSNs [83, 84]. Lee et al. [85] is an example of an RF charger utilizing WPH technology. The system was able to work with a minimum input power of −10 dBm (0.1 mW) in the frequency range from 1.96 to 1.98 GHz to charge a 5 V super-capacitor. Maximum RF to DC power conversion efficiency is 81% at 6 dBm (3.98 mW). Gudan et al. [86] also designed a WPH system to charge a NiMH battery using either ambient Wi-Fi or Bluetooth signals. With the sensitivity down to −20 dBm, this system was capable of charging a battery to 5.8 μJ after 1 h.
